

### DESCRIPTION

The MP4415A is a high-frequency, synchronous, rectified, step-down, switch-mode converter with built-in power MOSFETs. The MP4415A offers a very compact solution that achieves 1.5A of continuous output current with excellent load and line regulation over a wide input supply range. The MP4415A uses synchronous mode operation for higher efficiency over the output current load range.

Current mode operation provides fast transient response and eases loop stabilization.

Full protection features include over-current protection (OCP) and thermal shutdown.

The MP4415A requires a minimal number of readily available, standard external components, and is available in a space-saving QFN-13 (2.5mmx3mm) package.

### FEATURES

- Wide 4V to 36V Operating Input Range
- 1.5A Continuous Load Current
- 90mΩ/50mΩ Low  $R_{DS(ON)}$  Internal Power MOSFETs
- High-Efficiency Synchronous Mode Operation
- Default 2.2MHz Switching Frequency
- 450kHz to 2.2MHz Frequency Sync
- Forced Continuous Conduction Mode (CCM)
- Internal Soft Start (SS)
- Power Good (PG) Indicator
- Over-Current Protection (OCP) with Valley-Current Detection and Hiccup Mode
- Thermal Shutdown
- Output Adjustable from 0.8V
- CISPR25 Class 5 Compliant
- Available in a QFN-13 (2.5mmx3mm) Package

### APPLICATIONS

- Automotive
- Industrial Control Systems
- Medical and Imaging Equipment
- Telecom Applications
- Distributed Power Systems

All MPS parts are lead-free, halogen free, and adhere to the RoHS directive. For MPS green status, visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are registered trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

### TYPICAL APPLICATION

### ORDERING INFORMATION

Part Number*	Package	Top Marking
MP4415AGQB*	QFN-13 (2.5mmx3mm)	See Below

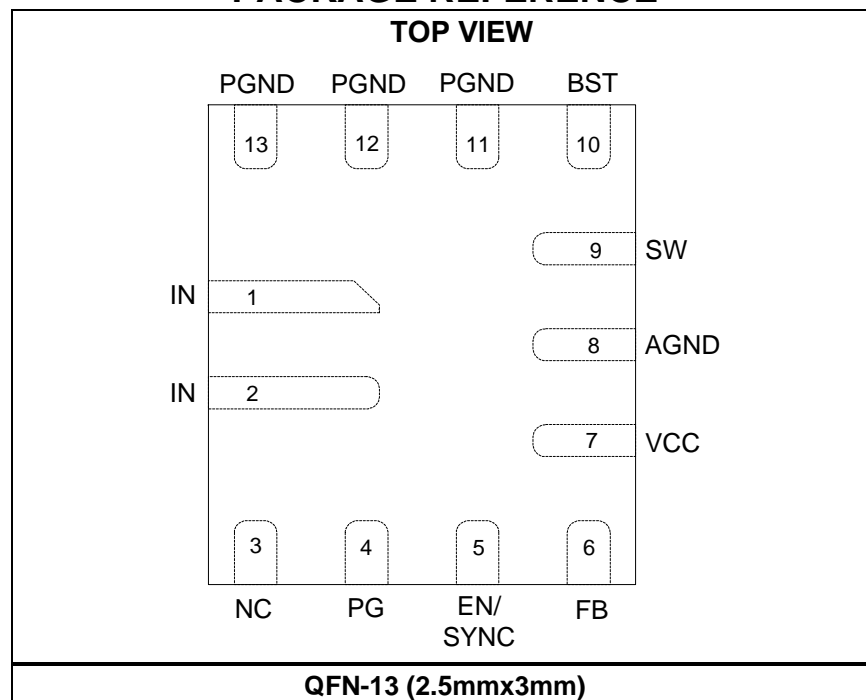

\* For Tape & Reel, add suffix -Z (e.g. MP4415AGQB-Z).

### PACKAGE REFERENCE

**ABSOLUTE MAXIMUM RATINGS** <sup>(1)</sup>

Supply voltage ( $V_{IN}$ )	-0.3V to +40V
Switch voltage ( $V_{SW}$ )	-0.3V to $V_{IN} + 0.3V$
BST voltage ( $V_{BST}$ )	$V_{SW} + 6V$
All other pins	-0.3V to +6V <sup>(2)</sup>
Continuous power dissipation ( $T_A = 25^\circ C$ ) <sup>(3)</sup>	
QFN-13 (2.5mmx3mm)	2.08W
Junction temperature	150°C
Lead temperature	260°C
Storage temperature	-65°C to +150°C

**Recommended Operating Conditions**

Supply voltage ( $V_{IN}$ )	4V to 36V
Output voltage ( $V_{OUT}$ )	0.8V to $V_{IN} * D_{MAX}$
Operating junction temp ( $T_J$ )	-40°C to +125°C

<b>Thermal Resistance</b> <sup>(4)</sup>	$\theta_{JA}$	$\theta_{JC}$
QFN-13 (2.5mmx3mm)	60.....	13... °C/W

**Notes:**

- 1) Absolute maximum ratings are rated under room temperature unless otherwise noted. Exceeding these ratings may damage the device.
- 2) For details on EN/SYNC's ABS max rating, see the Enable/SYNC section on page 12.
- 3) The maximum allowable power dissipation is a function of the maximum junction temperature  $T_J$  (MAX), the junction-to-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature  $T_A$ . The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_D$  (MAX) =  $(T_J$  (MAX) -  $T_A$ ) /  $\theta_{JA}$ . Exceeding the maximum allowable power dissipation produces an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 4) Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

$V_{IN} = 12V$ ,  $V_{EN} = 2V$ ,  $T_J = -40^{\circ}C$  to  $+125^{\circ}C$  <sup>(5)</sup>, unless otherwise noted, typical values are at  $T_J = +25^{\circ}C$ .

Parameter	Symbol	Condition	Min	Typ	Max	Units
Supply current (shutdown)	$I_{SHDN}$	$V_{EN} = 0V$			8	$\mu A$
Supply current (quiescent)	$I_Q$	$V_{EN} = 2V$ , $V_{FB} = 1V$ , no switching		0.6	0.8	mA
HS switch on resistance	$R_{ON\_HS}$	$V_{BST-SW} = 5V$		90	155	m $\Omega$
LS switch on resistance	$R_{ON\_LS}$	$V_{CC} = 5V$		50	105	m $\Omega$
Switch leakage	$I_{SW\_LKG}$	$V_{EN} = 0V$ , $V_{SW} = 12V$			1	$\mu A$

## PIN FUNCTIONS

Pin #	Name	Description
1, 2	IN	<b>Supply voltage.</b> IN supplies power for the internal MOSFET and regulator. The MP4415A operates from a 4V to 36V input rail. A low-ESR, low-inductance capacitor is required to decouple the input rail. Place the input capacitor very close to IN and connect it with wide PCB traces and multiple vias.
3	NC	<b>No connection.</b> Do not connect.
4	PG	<b>Power good indicator.</b> The output of PG is an open drain, and goes high if the output voltage exceeds 88% of the nominal voltage.
5	EN/SYNC	<b>Enable/synchronize.</b> Pull EN/SYNC high to enable the MP4415A. Float EN/SYNC or connect EN/SYNC to ground to disable the MP4415A. If an external sync clock is applied to EN/SYNC, the internal clock follows the sync frequency.
6	FB	<b>Feedback.</b> Connect FB to the tap of an external resistor divider from the output to AGND to set the output voltage. The frequency foldback comparator lowers the oscillator frequency when the FB voltage is below 400mV to prevent current limit runaway during a short-circuit fault. Place the resistor divider as close to FB as possible. Avoid placing vias on the FB traces.
7	VCC	<b>Internal bias supply.</b> Decouple VCC with a 0.1 $\mu$ F to 0.22 $\mu$ F capacitor. The capacitance should be no more than 0.22 $\mu$ F.
8	AGND	<b>Analog ground.</b> AGND is the reference ground of the logic circuit. AGND is connected to PGND internally. There is no need to add external connections to PGND.
9	SW	<b>Switch output.</b> Connect SW using a wide PCB trace.
10	BST	<b>Bootstrap.</b> A capacitor connected between SW and BST is required to form a floating supply across the high-side switch driver. A 20 $\Omega$ resistor placed between the SW and BST capacitor is strongly recommended to reduce SW voltage spikes.
11, 12, 13	PGND	<b>Power ground.</b> PGND is the reference ground of the power device, and requires careful consideration during PCB layout. For best results, connect PGND with copper pours and vias.

### FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram

## OPERATION

The MP4415A is a high-frequency, synchronous, rectified, step-down, switch-mode converter with built-in power MOSFETs. The MP4415A offers a very compact solution that achieves 1.5A of continuous output current with excellent load and line regulation over a 4V to 36V input supply range.

The MP4415A operates in fixed-frequency, peak current control mode to regulate the output voltage. An internal clock initiates a pulse-width modulation (PWM) cycle. The integrated high-side power MOSFET (HS-FET) turns on and remains on until the current reaches the value set by the COMP voltage ( $V_{COMP}$ ). When the power switch is off, it remains off until the next clock cycle begins. If the current in the power MOSFET does not reach the value set by  $V_{COMP}$  within 85% of one PWM period, the power MOSFET is forced off.

### Internal Regulator

A 4.9V internal regulator powers most of the internal circuitries. This regulator takes  $V_{IN}$  as the input and operates in the full  $V_{IN}$  range. When  $V_{IN}$  exceeds 4.9V, the output of the regulator is in full regulation. When  $V_{IN}$  falls below 4.9V, the output decreases following  $V_{IN}$ . A 0.1 $\mu$ F decoupling ceramic capacitor is required at VCC.

### Continuous Conduction Mode (CCM) Operation

The MP4415A uses continuous conduction modulation (CCM) mode to ensure that the part works with a fixed frequency from a no-load to full-load range. The advantage of CCM is the controllable frequency and lower output ripple at light load.

### Frequency Foldback

The MP4415A enters frequency foldback when the input voltage exceeds 21V. The frequency decreases to half the nominal value and changes to 1.1MHz.

Frequency foldback also occurs during soft start and short-circuit protection.

### Error Amplifier (EA)

The error amplifier (EA) compares the FB voltage to the internal 0.807V reference ( $V_{REF}$ )

and outputs a current proportional to the difference between the two. This output current then charges or discharges the internal compensation network to form  $V_{COMP}$ , which controls the power MOSFET current. The optimized internal compensation network minimizes the external component count and simplifies the control loop design.

### Under-Voltage Lockout (UVLO)

Under-voltage lockout (UVLO) protects the chip from operating at an insufficient supply voltage. The UVLO comparator monitors the output voltage of the internal regulator (VCC). The UVLO rising threshold is about 3.5V with a 330mV hysteresis.

### Enable/SYNC

EN/SYNC is a control pin that turns the regulator on and off. Drive EN/SYNC high to turn on the regulator; drive EN/SYNC low to turn it off. An internal 400k $\Omega$  resistor from EN/SYNC to GND allows EN/SYNC to be floated to shut down the chip.

EN/SYNC is clamped internally using a 6.5V series Zener diode (see Figure 2). Connecting the EN/SYNC input through a pull-up resistor to the voltage on  $V_{IN}$  limits the EN input current to less than 100 $\mu$ A. For example, with 12V connected to  $V_{IN}$ ,  $R_{PULLUP} \geq (12V - 6.5V) \div 100\mu A = 55k\Omega$ .

Connecting EN/SYNC directly to a voltage source without a pull-up resistor requires limiting the amplitude of the voltage source to  $\leq 6V$  to prevent damage to the Zener diode.

Figure 2: 6.5V Zener Diode Connection

Connect an external clock with a range of 450kHz to 2.2MHz to synchronize the internal clock rising edge to the external clock rising edge. The pulse width of the external clock signal should be below 350ns. The off time of the external clock signal should be below 1.9 $\mu$ s.

### Internal Soft Start (SS)

Soft start (SS) prevents the converter output voltage from overshooting during start-up. When the chip starts up, the internal circuitry generates a soft-start voltage ( $V_{SS}$ ). When  $V_{SS}$  is below the internal reference ( $V_{REF}$ ),  $V_{SS}$  overrides  $V_{REF}$ , so the error amplifier uses  $V_{SS}$  as the reference. When  $V_{SS}$  exceeds  $V_{REF}$ , the error amplifier uses  $V_{REF}$  as the reference. The SS time is internally set to 1.5ms.

### Power Good (PG)

The MP4415A has a power good (PG) indicator. PG is the open drain of a MOSFET, and should be connected to VCC or another voltage source through a resistor (e.g. 100k $\Omega$ ). In the presence of an input voltage, the MOSFET turns on, and PG is pulled low before SS is ready. After  $V_{FB}$  reaches 88% of  $V_{REF}$ , there is a delay (typically 90 $\mu$ s) and PG is pulled high. When  $V_{FB}$  drops to 83% of  $V_{REF}$ , PG is pulled low. PG is also pulled low if a thermal shutdown occurs or EN/SYNC is pulled low.

### Over-Current Protection (OCP) and Hiccup Mode

The MP4415A has cycle-by-cycle peak current-limit protection and valley-current detection protection. The inductor current is monitored during the HS-FET on state. If the inductor current exceeds the current-limit value set by the COMP high-clamp voltage, the HS-FET turns off immediately. Then the low-side MOSFET (LS-FET) turns on to discharge the energy, and the inductor current decreases.

The HS-FET remains off until the inductor valley current falls below the valley current limit, even if the internal clock pulses high. If the inductor current does not drop below the valley current limit when the internal clock pulses high, the HS-FET misses the clock, and the switching frequency decreases to half the nominal value. Both the peak and valley current limits help keep the inductor current from running away during an overload or short-circuit condition.

If the output voltage drops below the under-voltage (UV) threshold (typically 50% below the reference), the peak current limit is kicked simultaneously, and the MP4415A enters hiccup mode to restart the part periodically.

This protection mode is useful when the output is dead-shortened to ground, and reduces the average short-circuit current greatly to alleviate thermal issues and protect the regulator. The MP4415A exits hiccup mode once the over-current condition is removed.

### Thermal Shutdown

Thermal shutdown prevents the chip from operating at exceedingly high temperatures. When the die temperature exceeds 170 $^{\circ}$ C, the entire chip shuts down. When the temperature drops below its lower threshold (typically 140 $^{\circ}$ C), the chip is enabled again.

### Floating Driver and Bootstrap Charging

An external bootstrap capacitor powers the floating power MOSFET driver. The floating driver has its own UVLO protection, with a rising threshold of 2.2V and hysteresis of 150mV. A dedicated internal regulator charges and regulates the bootstrap capacitor voltage to about 5V (see Figure 3). When the voltage between the BST and SW nodes drops below regulation, a PMOS pass transistor connected from  $V_{IN}$  to BST turns on. The charging current path is from  $V_{IN}$  to BST, and then to SW. The external circuit should provide enough voltage headroom to facilitate charging.

As long as  $V_{IN}$  is significantly higher than SW, the bootstrap capacitor remains charged. When the HS-FET is on,  $V_{IN} \approx V_{SW}$ , so the bootstrap capacitor cannot be charged. When the LS-FET is on,  $V_{IN} - V_{SW}$  reaches its maximum for fast charging. When there is no inductor current,  $V_{SW} = V_{OUT}$ , so the difference between  $V_{IN}$  and  $V_{OUT}$  can charge the bootstrap capacitor. A 20 $\Omega$  resistor placed between SW and the BST capacitor is strongly recommended to reduce SW voltage spikes.

**Figure 3: Internal Bootstrap Charging Circuit**

### **Start-Up and Shutdown**

If both  $V_{IN}$  and EN/SYNC exceed their thresholds, the chip starts up. The reference block starts first, generating a stable reference voltage and current, and then the internal regulator is enabled. The regulator provides a stable supply for the remaining circuitries.

Three events can shut down the chip:  $V_{IN}$  low, EN/SYNC low, and thermal shutdown. During the shutdown procedure, the signaling path is blocked first to avoid any fault triggering.  $V_{COMP}$  and the internal supply rail are then pulled down. The floating driver is not subject to this shutdown command.

## APPLICATION INFORMATION

### Setting the Output Voltage

The external resistor divider connected to FB sets the output voltage (see Figure 4). The feedback resistor (R1) also sets the feedback loop bandwidth with the internal compensation capacitor. Choose  $R_{FB1}$  to be about 40k $\Omega$  when  $V_{OUT} \geq 1V$ .  $R_{FB2}$  can then be calculated with Equation (1):

$$R_{FB2} = \frac{R_{FB1}}{\frac{V_{OUT}}{0.807V} - 1} \quad (1)$$

A T-type network is highly recommended when  $V_{OUT}$  is low (see Figure 4).

**Figure 4: T-Type Feedback Network**

$R_T + R_{FB1}$  is used to set the loop bandwidth. The lower  $R_T + R_{FB1}$  is, the higher the bandwidth. However, a high bandwidth may cause an insufficient phase margin, resulting in loop instability. Therefore, a proper  $R_T$  value is required to make a trade-off between the bandwidth and phase margin. Table 1 lists the recommended feedback resistor and  $R_T$  values for common output voltages.

**Table 1: Resistors for Common Output Voltages**

$V_{OUT}$ (V)	$R_{FB1}$ (k $\Omega$ )	$R_{FB2}$ (k $\Omega$ )	$R_T$ (k $\Omega$ )
3.3	41.2 (1%)	13 (1%)	20 (1%)
5	41.2 (1%)	7.68 (1%)	20 (1%)

### Selecting the Input Capacitor

The step-down converter has a discontinuous input current, and requires a capacitor to supply AC current to the converter while maintaining the DC input voltage. For the best performance, use low-ESR capacitors. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients.

For most applications, use a 4.7 $\mu$ F to 10 $\mu$ F capacitor. It is strongly recommended to use another, lower value capacitor (e.g. 0.1 $\mu$ F) with a small package size (0603) to absorb high-frequency switching noise. Place the smaller capacitor as close to IN and GND as possible.

Since  $C_{IN}$  absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in the input capacitor can be estimated with Equation (2):

$$I_{CIN} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \quad (2)$$

The worst-case condition occurs at  $V_{IN} = 2V_{OUT}$ , calculated with Equation (3):

$$I_{CIN} = \frac{I_{LOAD}}{2} \quad (3)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality ceramic capacitor (e.g. 0.1 $\mu$ F) as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide a sufficient charge to prevent excessive voltage ripple at input. The input voltage ripple caused by the capacitance can be estimated with Equation (4):

$$\Delta V_{IN} = \frac{I_{LOAD}}{f_{SW} \times C_{IN}} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (4)$$

### Selecting the Output Capacitor

The output capacitor maintains the DC output voltage. Use ceramic, tantalum, or low-ESR electrolytic capacitors. For best results, use low-ESR capacitors to keep the output voltage ripple low. The output voltage ripple can be estimated with Equation (5):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L} \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \cdot \left(R_{ESR} + \frac{1}{8f_{SW} \times C_{OUT}}\right) \quad (5)$$

Where L is the inductor value, and  $R_{ESR}$  is the equivalent series resistance (ESR) value of the output capacitor.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency, and the capacitance causes the majority of the output voltage ripple. For simplification, the output voltage ripple can be estimated with Equation (6):

$$\Delta V_{OUT} = \frac{V_{OUT}}{8 \times f_{SW}^2 \times L \times C_{OUT}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (6)$$

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be approximated with Equation (7):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times R_{ESR} \quad (7)$$

The characteristics of the output capacitor also affect the stability of the regulation system. The MP4415A can be optimized for a wide range of capacitance and ESR values.

### Selecting the Inductor

A 1μH to 10μH inductor with a DC current rating at least 25% above the maximum load current is recommended for most applications. For higher efficiency, choose an inductor with a lower DC resistance. A higher value inductor results in less ripple current and a lower output ripple voltage, but also has a larger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductor value is to allow the inductor ripple current to be approximately 30% of the maximum load current. The inductance value can then be calculated with Equation (8):

$$L = \frac{V_{OUT}}{f_{SW} \times \Delta I_L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (8)$$

Where  $\Delta I_L$  is the peak-to-peak inductor ripple current.

Choose the inductor ripple current to be approximately 30% of the maximum load current. The maximum inductor peak current can be calculated with Equation (9):

$$I_{LP} = I_{LOAD} + \frac{V_{OUT}}{2f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (9)$$

### V<sub>IN</sub> UVLO Setting

The MP4415A has an internal, fixed under-voltage lockout (UVLO) threshold. The rising threshold is 3.5V, and the falling threshold is about 3.17V. For applications that require a higher UVLO point, an external resistor divider between IN and EN/SYNC can be used to achieve a higher equivalent UVLO threshold (see Figure 5).

**Figure 5: Adjustable UVLO using EN Divider**

The UVLO threshold can be calculated with Equation (10) and Equation (11):

$$INUV_{RISING} = \left(1 + \frac{R_{UP}}{400k\Omega \cdot R_{DOWN}}\right) \times V_{EN\_RISING} \quad (10)$$

$$INUV_{FALLING} = \left(1 + \frac{R_{UP}}{400k\Omega \cdot R_{DOWN}}\right) \times V_{EN\_FALLING} \quad (11)$$

Where  $V_{EN\_RISING} = 1.45V$ , and  $V_{EN\_FALLING} = 1V$ .

When choosing  $R_{UP}$ , ensure that it is large enough to limit the current flowing into EN/SYNC below 100μA.

### BST Resistor and External BST Diode

A 20Ω resistor in series with the BST capacitor is recommended to reduce SW voltage spikes. A higher resistance is better for SW spike reduction, but also compromises efficiency.

An external BST diode can enhance the efficiency of the regulator when the duty cycle is high (>65%). A power supply between 2.5V and 5V can be used to power the external bootstrap diode. VCC or V<sub>OUT</sub> is recommended for this power supply in the circuit (see Figure 6).

**Figure 6: Optional External Bootstrap Diode to Enhance Efficiency**

The recommended external BST diode is 1N4148, and the recommended BST capacitor value is 0.1 $\mu$ F to 1 $\mu$ F.

**PCB Layout Guidelines <sup>(8)</sup>**

Efficient PCB layout, especially regarding input capacitor placement, is critical for stable operation. A 4-layer layout is strongly recommended to achieve better thermal performance. For best results, refer to Figure 7 and follow the guidelines below:

1. Use a large ground plane to connect directly to PGND. If the bottom layer is a ground plane, add vias near PGND.
2. Ensure that the high-current paths at GND and IN have short, direct, and wide traces.
3. Place the ceramic input capacitor, especially the small-sized input bypass capacitor (0603), as close to IN and PGND as possible to minimize high-frequency noise.
4. Keep the connection to the input capacitor and IN as short and wide as possible.
5. Place the VCC capacitor as close to VCC and AGND as possible.
6. Route SW and BST away from sensitive analog areas such as FB.
7. Place the feedback resistors close to the chip to ensure that the trace connecting to FB is as short as possible.
8. Use multiple vias to connect the power planes to internal layers.

**Note:**

8) The recommended layout is based on Figure 7.

**Top Layer**

**Inner Layer 1**

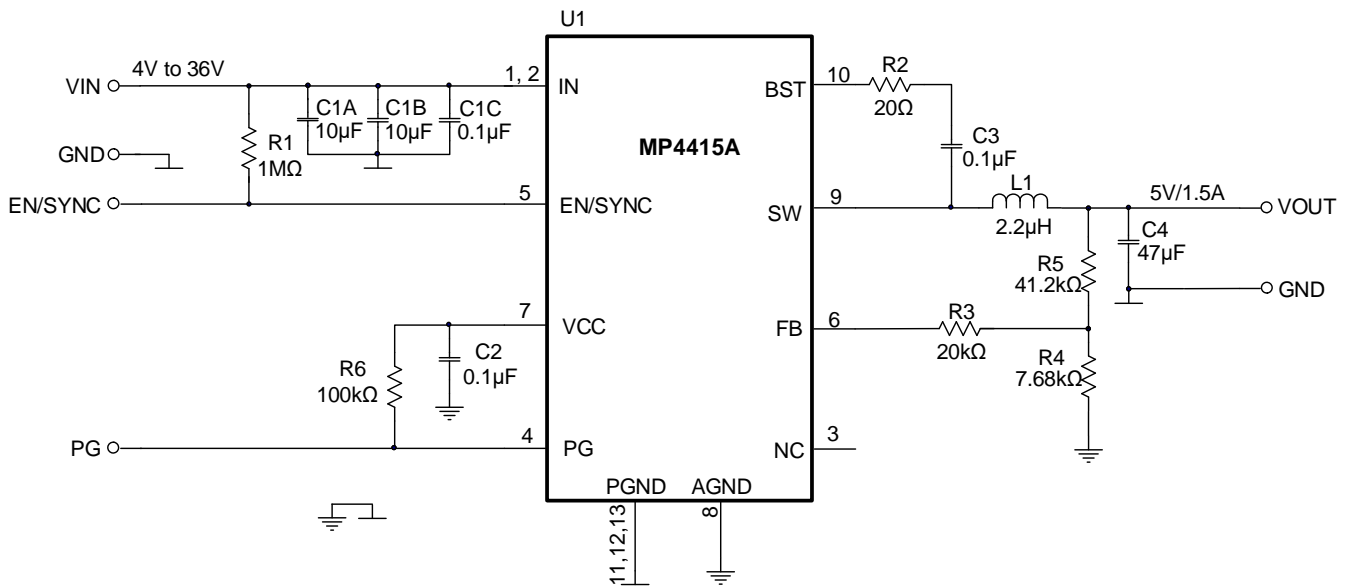

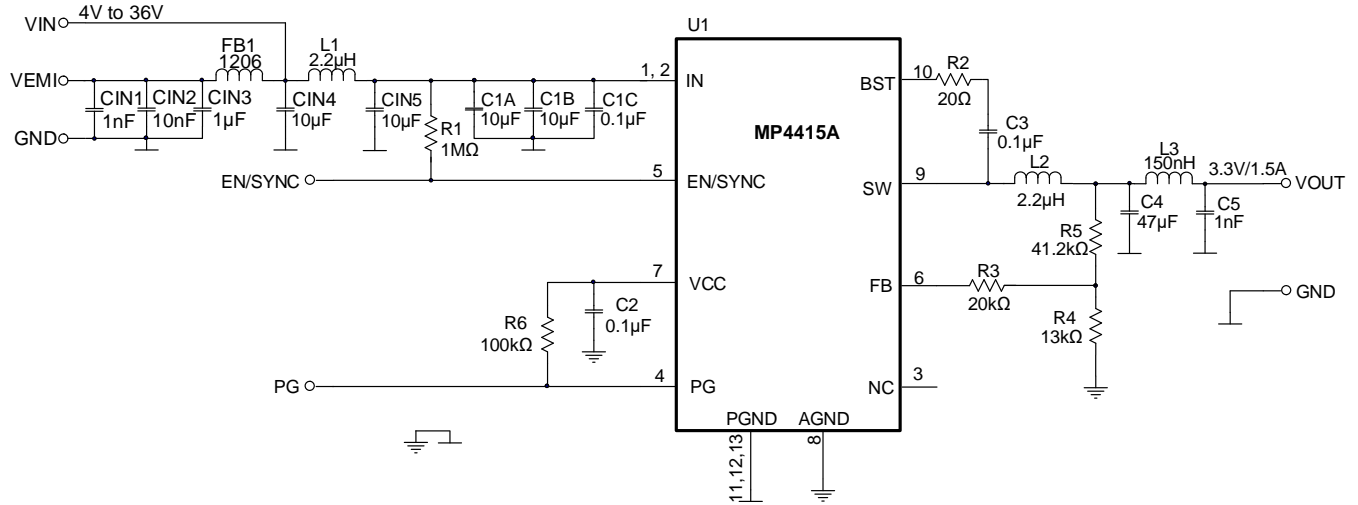

**Inner Layer 2**

**Bottom Layer**
