MP1907

100V, 2.5A, High Frequency Half-bridge Gate Driver

The Future of Analog IC Technology

DESCRIPTION

The MP1907 is a high frequency, 100V half bridge N-channel power MOSFET driver. Its low side and high side driver channels are independently controlled and matched with less than 5ns in time delay. Under-voltage lock-out both high side and low side supplies force their outputs low in case of insufficient supply. Both outputs will remain low until a rising edge on either input is detected. The integrated bootstrap diode reduces external component count.

FEATURES

- Drives N-channel MOSFET half bridge
- 100V V_{BST} voltage range
- Input signal overlap protection
- On-chip bootstrap diode
- Typical 20ns propagation delay time
- Less than 5ns gate drive mismatch
- Drive 1nF load with 12ns/9ns rise/fall times with 12V VDD
- TTL compatible input
- Less than 150μA quiescent current
- Less than 5μA shutdown current
- UVLO for both high side and low side
- In 3×3mm QFN10 Packages

APPLICATIONS

- Battery Powered Hand Tool
- Telecom half bridge power supplies
- Avionics DC-DC converters
- Active-clamp Forward Converters

SW Voltage (V_{SW}) .....-1.0V to 100V
SW slew rate.....<50V/nsec
Operating Junction Temp. (T_J). -40°C to +125°C

Thermal Resistance (5)

	θ_{JA}	θ_{JC}	
QFN10 (3x3)	50	12	°C/W

Notes:

1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA}, and the ambient temperature T_A. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J (MAX)-T_A)/θ_{JA}. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) 4.5V is only a typical value for minimum supply voltage at V_{DD} falling
5) Measured on JESD51-7, 4-layer PCB.

PIN FUNCTIONS

Package Pin #	Name	Description
1	VDD	Supply input. This pin supplies power to all the internal circuitry. A decoupling capacitor to ground must be placed close to this pin to ensure stable and clean supply.
2	NC	No Connection.
3	BST	Bootstrap. This is the positive power supply for the internal floating high-side MOSFET driver. Connect a bypass capacitor between this pin and SW pin.
4	DRVH	Floating driver output.
5	SW	Switching node.
6	EN	On/off Control.
7	INH	Control signal input for the floating driver.
8	INL	Control signal input for the low side driver.
9	VSS, Exposed Pad	Chip ground. Connect to Exposed pad to VSS for proper thermal operation.
10	DRVL	Low side driver output.

OPERATION

Switch Shoot-through Protection

The input signals of INH and INL are controlled independently. Input shoot-through protection circuitry is implemented to prevent shoot-through between the HSFET and LSFET outputs. Only one of the FET drivers can be ON at one time. If both INH and INL are high at the same time, both HSFET and LSFET will be OFF.

Under Voltage Lock Out

When VDD or BST goes below their respective UVLO thresholds, both DRVH and DRVL outputs will go low to turn off both FETs. Once VDD rises above the UVLO threshold, both DRVH and DRVL will stay low until a rising edge is detected on either INH or INL.

The truth table in Table 1 details the operation of the HSFET and LSFET under different INH, INL and UVLO conditions

Reference Design Circuits

Half Bridge Motor Driver

T In half-bridge converter topology, the MOSFETs are driven alternately with some dead time. Therefore, INH and INL are driven with alternating signals from the PWM controller. The input voltage can be up to 100V in this application.

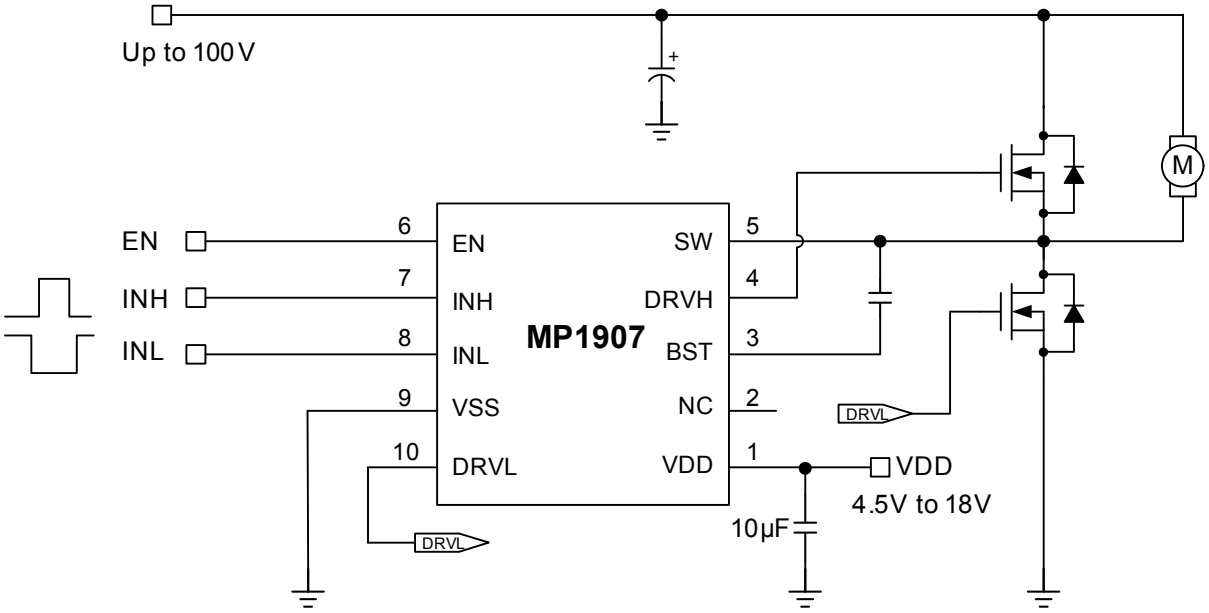

Figure 3—Half-Bridge Motor Driver

Active-Clamp Forward Converter

In active-clamp forward converter topology, the MOSFETs are driven alternately. The high-side MOSFET, along with capacitor C_{reset}, is used to reset the power transformer in a lossless manner. This topology lends itself well to run at duty cycles exceeding 50%. For these reasons, the input voltage may not be able to run at 100V for this application.
