BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.15.81 reg_LLP_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

21.15.90 reg_SGR_type (SGR6)—Offset 258h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

21.15.92 reg_SAR_type (SAR7)—Offset 268h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT : Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE : If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS : Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

21.15.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmask the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. 7:0	0h WO	CLEAR: Interrupt clear. 0 = no effect 1 = clear interrupt

21.15.122 reg_Clear_type (ClearSrcTran)—Offset 348h

Each bit in the Raw Status and Status registers is cleared on the same cycle by writing a 1 to the corresponding location in the Clear registers: ClearBlock, ClearDstTran, ClearErr, ClearSrcTran, and ClearTfr. Each Interrupt Clear register has a bit allocated per channel, for example, ClearTfr(2) is the clear bit for the Channel 2 transfer complete interrupt. Writing a 0 has no effect. These registers are not readable.

Access Method

15:8	0h WO	CH_EN_WE: Channel enable write enable.
7:0	0h RW	CH_EN: Enables/Disables the channel. Setting this bit enables a channel, clearing this bit disables the channel. 0 = Disable the Channel 1 = Enable the Channel The ChEnReg.CH_EN bit is automatically cleared by hardware to disable the channel after the last OCP transfer of the DMA transfer to the destination has completed. Software can therefore poll this bit to determine when this channel is free for a new DMA transfer.

21.16.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

SAR0: [BAR + 9C000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.2 reg_DAR_type (DAR0)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

CH_CLASS				CH_WEIGHT				DONE		BLOCK_TS													

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT : Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE : If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS : Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

21.16.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.15 reg_DAR_type (DAR1)—Offset 60h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

21.16.16 reg_LLP_type (LLP1)—Offset 68h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

21.16.19 reg_SSTAT_type (SSTAT1)—Offset 78h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.28 reg_DAR_type (DAR2)—Offset B8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length = 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.29 reg_LL2_type (LLP2)—Offset C0h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled. The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer—single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

CH_CLASS				CH_WEIGHT				DONE		BLOCK_TS													

Bit Range	Default & Access	Description
31:29	0h RW	CH_CLASS: Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT : Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE : If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS : Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

Bit Range	Default & Access	Description
31:0	0h RW	DAR: Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.42 reg_LLP_type (LLP3)—Offset 118h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

21.16.45 reg_SSTAT_type (SSTAT3)—Offset 128h

31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT : Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE : If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS : Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

21.16.58 reg_SSTAT_type (SSTAT4)—Offset 180h

BAR Type: PCI Configuration Register (Size: 32 bits)

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.68 reg_LLP_type (LLP5)—Offset 1C8h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

21.16.81 reg_LLp_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled. The LLP register has two functions: The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer—single or multi-block. Table shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

28:18	0h RW	CH_WEIGHT : Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS : Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. 21.16.92 reg_SAR_type (SAR7)—Offset 268h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:0	0h RW	SAR: Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

Bit Range	Default & Access	Description
28:18	0h RW	CH_WEIGHT: Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2 ¹¹ -1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	DONE: If status write-back is enabled, the upper word of the control register, CTL_HIin, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	BLOCK_TS: Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It doesnt mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2 ¹⁷ - 1) = (128 KB - 1).

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

21.16.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel *i* is memory, then the source transaction complete interrupt, MaskSrcTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel *i* is memory, then the destination transaction complete interrupt, MaskDstTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged.

Writing a 1 to any bit in these registers unmask the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

7:0	0h RW	INT_MASK : Interrupt mask 0-mask 1-unmask

21.16.119 reg_Mask_type (MaskErr)—Offset 330h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA channel *i* is memory, then the source transaction complete interrupt, MaskSrcTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel *i* is memory, then the destination transaction complete interrupt, MaskDstTran(*i*), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_*n*) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. Writing a 1 to any bit in these registers unmask the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

21.16.126 reg_DmaCfgReg_type (DmaCfgReg)—Offset 398h

This register is used to enable the DMA, which must be done before any channel activity can begin. If the global channel enable bit is cleared while any channel is still active, then DmaCfgReg.DMA_EN still returns 1 to indicate that there are channels still active until hardware has terminated all activity on all channels, at which point the DmaCfgReg.DMA_EN bit returns 0.

21.16.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, DmaCfgReg(0), is 0. When the global channel enable bit is 0, then a write to the ChEnReg register is ignored and a read will always read back 0. The channel enable bit, ChEnReg.CH_EN, is written only if the corresponding channel write enable bit, ChEnReg.CH_EN_WE, is asserted on the

same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

Software can therefore poll this bit to determine when this channel is free for a new DMA transfer.

22 Intel® Trusted Execution Engine (TXE)

This section describes the security components and capabilities of the Intel® Trusted Execution Engine (TXE) security co-processor.

Note: TXE firmware is required on the Bay Trail Platform as part of the PCU SPI flash image. PCU SPI must be setup in descriptor mode. For security reasons, primarily to lock PCU SPI flash access permission and OTP fuse programming, TXE Manufacturing Mode must be Disabled before shipping to customers. See your Intel® representative for details.

22.1 Features

22.1.1 Security Feature

The Intel® TXE is a security co-processor responsible for supporting and handling security. Features include:

- 32-bit RISC processor
- 256KB Data/Code RAM accessible only to the Intel® TXE
- 128KB On Chip Mask ROM for storage of Intel® TXE code
- Common Timer 1-100 μ S granularity, configurable interrupt (under FW control)
- Inter-Processor Communication for message passing between the Host CPU and Intel® TXE
- 64 byte input and output command buffers
- 256 byte shared payload (enables 2048-bit keys to be exchanged as part of the command)
- No Host CPU address domain access to the Intel® TXE address domain by any Host CPU address domain units
- Security controller has direct access to Host CPU address domain (Some Restrictions Apply). Multiple context DMA engine to transfer data between Host CPU address domain (System memory) and the Intel® TXE; programmable by the Intel® TXE CPU only.
- One multi-tiered FW Key Ladder and one Intel Key ladder.
- Paging DMA operations includes encryption/decryption and integrity check value (ICV) calculation. Auxiliary GPIOs to support input alert and two GP Outputs.

22.1.1.1 HW Accelerators

- DES/3DES (ECB, CBC) – 128b ABA key for 3DES Key Ladder Operations
- Three AES engines - Two fast -128 and one slow- 128/256

- Exponentiation Acceleration Unit (EAU) for modular exponentiation, modular reduction, large number addition, subtraction, and multiplication
- SHA1, SHA256/384/512, MD5

22.1.1.2 FW Utilities and Ciphers

- RSA (with EAU acceleration)
- Flash Write Enable/Disable
- Comprehensive IPC Command Set
- Chip Unique Key encryption key wrapping of other platform keys (Flash)

22.1.1.3 Downloadable FW Utilities and Ciphers

- Integrated Theft Deterrence Technology - Intel® Anti-Theft Technology (Intel® AT)
- Media Vault - content protection and distribution product specifically focused on online content for streaming and download
- One Time Programmable (OTP)

23:20	X RW	SEC_RST_CNT : Count of SeC Resets
19:16	X RW	SEC_CURR_OPER_MODE : The field indicates the firmware mode of operation during this boot cycle. The host must look at this field only after DRAM_INIT_DONE (DID) register based message unless the firmware is in ERR before sending the DID. The Operation Mode doesn't change at runtime. Possible values: 0: Normal. SeC is running in normal mode. 1: Reserved. 2: Debug mode. SeC firmware enters this operation mode when SeC firmware FLASH variable TBD is configured in FLASH to 1. Firmware stays in this mode until the SeC firmware FLASH variable TBD is set to 0. 3: Soft temporary disable. SeC firmware enters this operation mode when BIOS sends the Temporary Disable message to firmware. Firmware stays in this mode until BIOS sends a follow-up message to get SeC out of this mode. Entering this mode is not supported when the system is provisioned with Intel AT firmware. 4: SECOVR_JMPR: SeC firmware enters this operation mode when HDA_SDO asserts high. Asserting the HDA_SDO high on the rising edge of PWROK will also disable SeC and SeC applications. 5: SECOVR_HECI_MSG: SeC firmware enters this operation mode during the firmware image re-flash in the factory environments. BIOS sends the flash protection override message (HMRFP0 ENABLE HECI command) and causes a global reset then SeC firmware stays in this state similar to 'Soft Temporary Disable'. Before sending End of Post message (at late POST timeframe), BIOS needs to send a HMRFP0 DISABLE command if SECOVR_HECI_MSG is set. In the same boot, the user can flash an image and reset (global reset or G3- exit) the system that will cause firmware to boot with a normal mode.
15:12	X RW	ERR_CODE : Set to a nonzero value if the firmware has encountered a fatal error. The firmware has stopped normal operation. Encoding as follows: 0: No error. Firmware is operational in current state. 1: Uncategorized Failure. SeC firmware has experienced an uncategorized error and has disabled itself. Further details of the failure can be found in field FW_STS1.EXT_STAT_DAT. This state can only be exited by powering down or resetting the machine. 2: Reserved. 3: Image Failure. SeC firmware stored in the system flash is not valid. If supported by the platform, the host should program a full firmware image into SeC flash region through the SPI controller. After completion of the SeC flash region update, the host should generate a full system reset the platform (global reset). 4: Debug Failure. Set when more data is available to the firmware on the cause of the failure. Please refer to field FW_STS1.EXT_STAT_DAT_CURR_STATE for more details. 5: Internal ROM Error. 6: Invalid fuse configuration. 7: Failure to access SPI FLASH.
11	X RW	FW_UPD_IN_PROG : This bit is set when data migration is required during the Firmware-update process.

Bit Range	Default & Access	Field Name (ID): Description
10	X RW	FW_BUP_LD_FLR: This bit is set when firmware is not able to load BRINGUP from the fault tolerant (FT) code. When this bit set, it may or may not have the error code shown in field ERR_CODE. The reason is because the firmware can load BRINGUP from the non fault tolerant (NFT) code.
9	X RW	FW_INIT_COMP: When this bit is clear, firmware is still in loading process and has not made it to final steady state yet. When firmware has fully entered a stable state, this bit is set to 1 and 'Current Working State' field of this register provides the steady state of SeC.
8:6	000b RW	SEC_CURR_OP_STATE: This field describes the state in which SeC is currently functioning in at this moment. It's the combination of SeC power state and UMA. The field is set only upon entering the true hardware state. Values: 000b: Preboot (default) 001b: M0 with UMA. 010b: M0ff. 011b: Reserved. 100b: Reserved. 101b: Reserved. 110b: Bringup. 111b: M0 without UMA but with error. If there is no memory in the system, or upon identifying an error in UMA initialization, the SeC firmware will get into this operation state.
5	X RW	FPT_BAD: This bit is set when the firmware discovers a bad checksum of Flash Partition Table (FPT). When this bit set, it may or may not have the error code shown in field ERR_CODE. The system can get this bit clear by flashing the proper firmware image again.
4	X RW	MANUF_MODE: When this bit is set, the platform is still in Manufacturing mode. Host can use this bit to inform user that the platform is NOT ready for production yet. This bit is set as long as SeC Manufacturing Mode Done bit is set to 0 or SPI flash descriptor region is not locked. For shipping machine, this bit has to be to 0.
3:0	X RW	SEC_CURR_WRK_STATE: This field describes the current working state of the SeC firmware. Further information about the progress within the Current Working State can be found in field SEC_FW_STS1.EXT_STS_DAT. In spoken language, the 'Current Working State' indicates what firmware is doing at this moment. Encoding is as follows: 0: Reset. SeC firmware is in a reset state. 1: Initializing. SeC firmware is initializing, the final functional state is NOT known at this time. 2: Recovery: SeC firmware is recovering from an image update failure. Upon completion of this state, SeC firmware will enter the Initializing State. The firmware will stay in recovery state until a new firmware update is run. 3: Reserved. 4: Reserved. 5: Normal. SeC firmware is operating in normal state. 6: Platform Disable Wait. SeC firmware enters this state when it pauses itself with AT fuses set to halt platform after 30 minutes wait. 7: OP State Transition. SeC firmware sets this state before starting a transition to a new operation state. 8: Reserved.

23 PCI Express* 2.0

There are four lanes and up to four PCI Express root ports, each supporting the *PCI Express* Base Specification*, Rev. 2.0 at a maximum 5 GT/s signaling rate. The root ports can be configured to support a diverse set of lane assignments.

23.1 Signal Descriptions

Please see [Chapter 2, "Physical Interfaces"](#) for additional details.

The signal description table has the following headings:

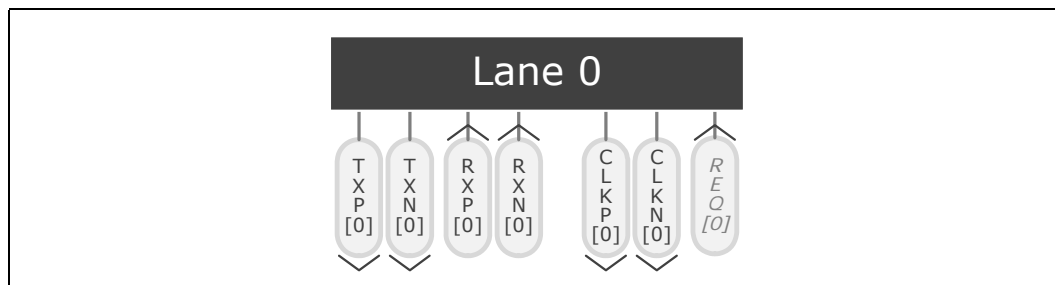

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal's function

Note: PMC_WAKE_PCIE[3:0]# are not listed, but can be used by PCI Express* devices. Please see [Section 30, "PCU – Power Management Controller \(PMC\)"](#) on page 4299 for details.

Table 238. Signals

Signal Name	Direction Plat. Power	Description
PCIE_TXP[3:0] PCIE_TXN[3:0]	O PCIESATA	PCI Express* Transmit PCI Express* Ports 3:0 transmit pair (P and N) signals. Each pair makes up the transmit half of a lane.
PCIE_RXP[3:0] PCIE_RXN[3:0]	I PCIESATA	PCI Express* Receive: PCI Express* Ports 3:0 receive pair (P and N) signals. Each pair makes up the receive half of lane.
PCIE_CLKP[3:0] PCIE_CLKN[3:0]	O V1P0S	PCI Express* Output Clock 100-MHz differential clock signals. These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock.
PCIE_CLKREQ[3:0]#	I V1P8S	PCI Express* Clock Request Used for devices that need to request one of the four output clocks. Each clock request maps to the matching clock output (e.g., PCI_CLKREQ[0] maps to PCIE_CLKP/N[0]). These are not owned by the PCI Express* controller, but are platform clocks found in the Integrated Clock. <i>These signals are muxed and may be used by other functions.</i>
PCIE_RCOMP_P PCIE_RCOMP_N	I/O	These pins are used to connect the external resistors used for Rcomp. Please contact your Intel representative for details.

23.2 Features

- Conforms to *PCI Express* Base Specification, Rev. 2.0*
- 5.0 or 2.5 GT/s operation per root port
- Virtual Channel support for VC0
- x1, x2 and x4 link widths (auto negotiated)
- Flexible Root Port (1-4) configuration options
 - (4) x1's

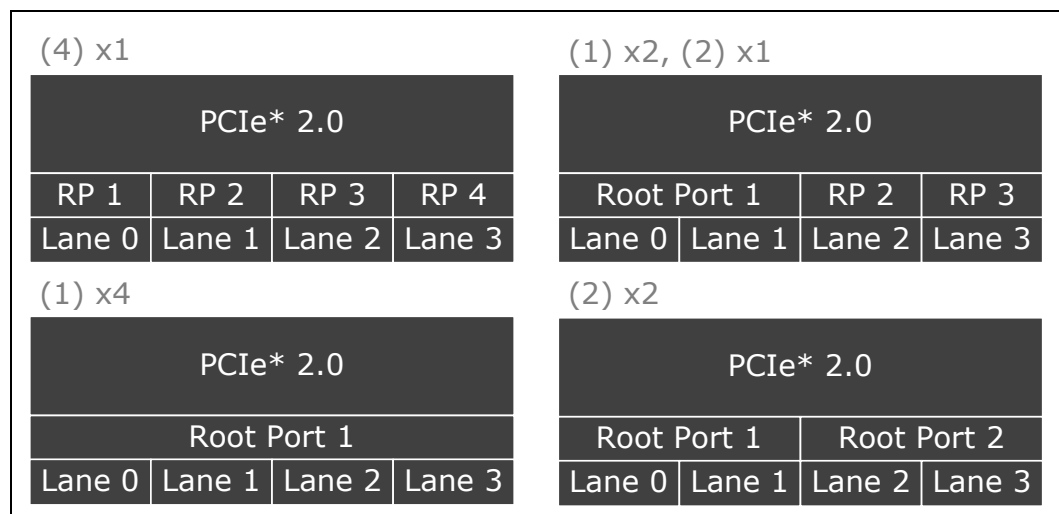

- (2) x2’s
- (1) x2 plus (2) x1’s
- (1) x4
- Interrupts and Events
 - Legacy (INTx) and MSI Interrupts
 - General Purpose Events
 - Express Card Hot Plug Events
 - System Error Events
- Power Management
 - Link State support for L0s, L1 and L2
 - Powered down in ACPI S3 state - L3

23.2.1 Root Port Configurations

Depending on SKU, there are up to four possible lane assignments for root ports 1-4.

Figure 115. Root Port Configuration Options

Root port configurations are set by SoftStraps stored in SPI flash, and the default option is "(4) x1". Links for each root port will train automatically to the maximum possible for each port.

Note: x2 link widths are not common. Most devices will only train to x1 or x4.

Note: PCI functions in PCI configuration space are disabled for root ports not available.

23.2.2 Interrupts and Events

A root port is capable of handling interrupts and events from an end point device. A root port can also generate its own interrupts for some events, including power management and hot plug events, but also including error events.

There are two interrupt types a root port will receive from an end point device: INTx (legacy), and MSI. MSI's are automatically passed upstream by the root port, just as other memory writes would be. INTx messages are delivered to the Legacy block's interrupt router/controller by the root port.

Events and interrupts that are handled by the root port are shown with the possible interrupts they can deliver to the interrupt decoder/router.

Table 239. Possible Interrupts Generated From Events/Packets

Packet/Event	Type	INTx	MSI	SERR	SCI	SMI	GPE
INTx	Packet	X	X				
PM_PME	Packet	X	X				
Power Management (PM)	Event	X	X		X	X	
Hot Plug (HP)	Event	X	X		X	X	
ERR_CORR	Packet			X			
ERR_NONFATAL	Packet			X			
ERR_FATAL	Packet			X			
Internal Error	Event			X			
VDM	Packet						X

Note: Table 239 lists the possible interrupts and events generated based on Packets received, or events generated in the root port. Configuration needed by software to enable the different interrupts as applicable.

When INTx interrupts are received by an end point, they are mapped to the following interrupts and sent to the interrupt decoder/router in the iLB:

Table 240. Interrupt Generated for INT[A-D] Interrupts

	INTA	INTB	INTC	INTD
Root Port 1	INTA#	INTB#	INTC#	INTD#
Root Port 2	INTD#	INTA#	INTB#	INTC#
Root Port 3	INTC#	INTD#	INTA#	INTB#
Root Port 4	INTB#	INTC#	INTD#	INTA#

Note: Interrupts generated from events within the root port are not swizzled.

23.2.2.1 Express Card Hot Plug Events

Express Card Hot Plug is available based on Presence Detection for each root port.

Note: A full Hot Plug Controller is not implemented.

Presence detection occurs when a PCI Express* device is plugged in and power is supplied. The physical layer will detect the presence of the device, and the root port will set the SLSTS.PDS and SLSTS.PDC bits.

When a device is removed and detected by the physical layer, the root port will clear the SLSTS.PDS bit, and set the SLSTS.PDC bit.

Interrupts can be generated by the root port when a hot plug event occurs. A hot plug event is defined as the transition of the SLSTS.PDC bit from 0 to 1. Software can set the SLCTL.PDE and SLTCTL.HPE bits to allow hot plug events to generate an interrupt.

If SLCTL.PDE and SLTCTL.HPE are both set, and STSTS.PDC transitions from 0 to 1, an interrupt will be generated.

23.2.2.2 System Error (SERR)

System Error events are support by both internal and external sources. See the PCI Express* Base Specification, Rev. 2.0 for details.

23.2.3 Power Management

Each root port's link supports L0s, L1, and L2/3 link states per PCI Express* Base Specification, Rev. 2.0. L2/3 is entered on entry to S3.

23.4 Register Map

Each root port supports its own extended PCI bridge header in PCI configuration space. These headers are located on PCI bus 0, device 28, functions 0-3 as shown below. There are no other registers implemented by the root ports or their controller.

See Chapters 3 and 4 for additional information.

23.5 PCI Configuration Registers

Registers listed are for function 0 (root port 1). All other root ports contain the same registers. Differences for other root ports (functions 1-3) will be noted in individual registers.

23.6.1 Identifiers (ID)—Offset 0h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

ID: [B:0, D:28, F:0] + 0h

Power Well: Core

Default: 00008086h

Bit Range	Default & Access	Description
31:16	0000h RO/V	Device Identification (DID): The value of this ID is product specific.
15:0	8086h RO	Vendor Identification (VID): Indicates Intel

Bit Range	Default & Access	Description
10	0b RW/V	Interrupt Disable (ID): This disables pin-based INTx# interrupts on enabled hot plug and power management events. This bit has no effect on MSI operation. When set, internal INTx# messages will not be generated. When cleared, internal INTx# messages are generated if there is an interrupt for hot plug or power management and MSI is not enabled. This bit does not affect interrupt forwarding from devices connected to the root port. Assert_INTx and Deassert_INTx messages will still be forwarded to the internal interrupt controllers if this bit is set. For PCI Bus Emulation Mode compatibility, if the PCIBEM register is set, this register is RO and returns a value of 0 when read, else it is RW with the functionality described above.
9	0b RO	Fast Back to Back Enable (FBE): Reserved per PCI-Express spec.
8	0b RW	SERR# Enable (SEE): When set, enables the root port to generate an SERR# message when PSTS.SSE is set.
7	0b RO	Wait Cycle Control (WCC): Reserved per PCI-Express spec.
6	0b RW	Parity Error Response Enable (PERE): Indicates that the device is capable of reporting parity errors as a master on the backbone.
5	0b RO	VGA Palette Snoop (VGA_PSE): Reserved per PCI-Express spec.
4	0b RO	Memory Write and Invalidate Enable (MWIE): Reserved per PCI-Express spec.
3	0b RO	Special Cycle Enable (SCE): Reserved per PCI-Express and PCI bridge spec.
2	0b RW	Bus Master Enable (BME): When set, allows the root port to forward Memory and I/O Read/Write cycles onto the backbone from a PCI-Express device. When this bit is 0b, Memory and I/O requests received at a Root Port must be handled as Unsupported Requests (UR). This bit does not affect forwarding of Completions in either the Upstream or Downstream direction. The forwarding of Requests other than Memory or I/O requests is not controlled by this bit.
1	0b RW	Memory Space Enable (MSE): When set, memory cycles within the range specified by the memory base and limit registers can be forwarded to the PCI-Express device. When cleared, these memory cycles are master aborted on the backbone.
0	0b RW	I/O Space Enable (IOSE): When set, I/O cycles within the range specified by the I/O base and limit registers can be forwarded to the PCI-Express device. When cleared, these cycles are master aborted on the backbone..

19	0b RW	VGA Enable (VE): When set, the following ranges will be claimed off the backbone by the root port: Memory ranges A0000h-BFFFFh I/O ranges 3B0h 3BBh and 3C0h 3DFh, and all aliases of bits 15:10 in any combination of 1's
18	0b RW	ISA Enable (IE): This bit only applies to I/O addresses that are enabled by the I/O Base and I/O Limit registers and are in the first 64KB of PCI I/O space. If this bit is set, the root port will block any forwarding from the backbone to the device of I/O transactions addressing the last 768 bytes in each 1KB block (offsets 100h to 3FFh).
17	0b RW	SERR# Enable (SE): When set, ERR_COR, ERR_NONFATAL, and ERR_FATAL messages received are forwarded to the backbone. When cleared, they are not.
16	0b RW	Parity Error Response Enable (PERE): When set, poisoned write TLPs and completions indicating poisoned TLPs will set the SSTS.DPD.

Bit Range	Default & Access	Description
15:8	00h RO/V	Interrupt Pin (IPIN) : Indicates the interrupt pin driven by the root port. 31	0b RW/C	Link Autonomous Bandwidth Status (LABS): This bit is Set by hardware to indicate that hardware has autonomously changed Link speed or width, without the Port transitioning through DL_Down status, for reasons other than to attempt to correct unreliable Link operation. This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was indicated as an autonomous change. The default value of this bit is 0b.
30	0b RW/C	Link Bandwidth Management Status (LBMS): This bit is Set by hardware to indicate that either of the following has occurred without the Port transitioning through DL_Down status: - A Link retraining has completed following a write of 1b to the Retrain Link bit Note: This bit is Set following any write of 1b to the Retrain Link bit, including when the Link is in the process of retraining for some other reason. - Hardware has changed Link speed or width to attempt to correct unreliable Link operation, either through an LTSSM timeout or a higher level process This bit must be set if the Physical Layer reports a speed or width change was initiated by the Downstream component that was not indicated as an autonomous change. The default value of this bit is 0b.
29	0b RO/V	Link Active (LA): Set to 1b when the Data Link Control and Management State Machine is in the DL_Active state, 0b otherwise.
28	0b RO/V	Slot Clock Configuration (SCC): In normal mode, root port uses the same reference clock as on the platform and does not generate its own clock. Note: The default of this register bit is dependent on the 'PCIe Non-Common Clock With SSC Mode Enable Strap'. If the strap enables non-common clock with SSC support, this bit shall default to '0'. Otherwise, this bit shall default to '1'.
27	0b RO/V	Link Training (LT): The root port sets this bit whenever link training is occurring, or that 1b was written to the Retrain Link bit but Link training has not yet begun. It clears the bit upon completion of link training.
26	0b RO	Reserved (RSVD): Reserved. Previously this was defined as Link Training Error (LTE) but support for this bit was removed from subsequent versions of the PCI Express specification.
25:20	00h RO/V	Negotiated Link Width (NLW): For the root ports, this register could take on several values: Port # Value of PN field RPC.PC1 00 01 10 11 1 01h 02h 02h 04h 2 01h 01h 01h 01h 3 01h 01h 02h 01h 4 01h 01h 01h 01h The value of this register is undefined if the link has not successfully trained.
19:16	1h RO/V	Current Link Speed (CLS): 0001b Link is 2.5Gb/s Link 0010b 5.0 GT/s Link The value of this field is undefined if the link is not up.
15:12	0h RO	Reserved (RSVD_1): Reserved
11	0b RW	Link Autonomous Bandwidth Interrupt Enable (LABIE): Link Autonomous Bandwidth Interrupt Enable - When Set, this bit enables the generation of an interrupt to indicate that the Link Autonomous Bandwidth Status bit has been Set.
10	0b RW	Link Bandwidth Management Interrupt Enable (LBMIE): When Set, this bit enables the generation of an interrupt to indicate that the Link Bandwidth Management Status bit has been Set. This bit is not applicable and is reserved for Endpoints, PCI Express-to-PCI/PCI-X bridges, and Upstream Ports of Switches. Functions that do not implement the Link Bandwidth Notification Capability must hardwire this bit to 0b. Default value of this bit is 0b.
9	0b RW	Hardware Autonomous Width Disable (HAWD): When Set, this bit disables hardware from changing the Link width for reasons other than attempting to correct unreliable Link operation by reducing Link width. Default value of this bit is 0b.
8	0b RO	Enable Clock Power Management (ECPM): Reserved. Not supported on Root Ports.
7	0b RW	Extended Synch (ES): When set, forces extended transmission of FTS ordered sets in FTS and extra TS2 at exit from L1 prior to entering L0.
6	0b RW	Common Clock Configuration (CCC): Reserved.

Bit Range	Default & Access	Description
5	0b WO	Retrain Link (RL) : When set, the root port will train its downstream link. This bit always returns '0' when read. Software uses LSTS.LT to check the status of training. It is permitted to write 1b to this bit while simultaneously writing modified values to other fields in this register. If the LTSSM is not already in Recovery or Configuration, the resulting Link training must use the modified values. If the LTSSM is already in Recovery or Configuration, the modified values are not required to affect the Link training that's already in progress.
4	0b RW	Link Disable (LD) : When set, the root port will disable the link by directing the LTSSM to the Disabled state.
3	0b RW/O	Read Completion Boundary Control (RCBC) : Indicates the read completion boundary is 64 bytes.
2	0b RO	Reserved (RSVD_2) : Reserved

BIOS should program this field to 00b or 10b during system initialization to advertise the level of hardware OBFF support to software. BIOS should never program this field to 01b or 11b since OBFF messaging is not supported.
17:12	00h RO	Reserved (RSVD_1): Reserved
11	1b RW/O	LTR Mechanism Supported (LTRMS): A value of 1b indicates support for the optional Latency Tolerance Reporting (LTR) mechanism capability. BIOS must write to this register with either a '1' or a '0' to enable/disable the root port from declaring support for the LTR capability.
10:5	00h RO	Reserved (RSVD_2): Reserved
4	1b RO	Completion Timeout Disable Supported (CTDS): A value of 1b indicates support for the Completion Timeout Disable mechanism.
3:0	6h RO	Completion Timeout Ranges Supported (CTRS): This field indicates device support for the optional Completion Timeout programmability mechanism. This mechanism allows system software to modify the Completion Timeout value. This field is applicable only to Root Ports, Endpoints that issue requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of requests issued on PCI Express. For all other devices this field is reserved and must be hardwired to 0000b. Four time value ranges are defined: Range A: 50us to 10ms Range B: 10ms to 250ms Range C: 250ms to 4s Range D: 4s to 64s Bits are set according to the table below to show timeout value ranges supported. 0000b Completion Timeout programming not supported. 0001b Range A 0010b Range B 0011b Ranges A [amp] B 0110b Ranges B [amp] C [lt]-- This is supported 0111b Ranges A, B [amp] C 1110b Ranges B, C [amp] D 1111b Ranges A, B, C [amp] D All other values are reserved.

Note: Only encoding 00b and 11b are supported. The encoding of 01b or 10b would be aliased to 00b. If DCAP2.OBFEN is clear, programming this field to any non-zero values will have no effect.
12:11	00b RO	Reserved (RSVD_2): Reserved
10	0b RW	LTR Mechanism Enable (LTREN): When Set to 1b, this bit enables the Latency Tolerance Reporting (LTR) mechanism. For Downstream Ports, this bit must be reset to the default value if the Port goes to DL_Down status. If DCAP2.LTRMS is clear, programming this field to any non-zero values will have no effect.
9:5	00h RO	Reserved (RSVD_3): Reserved
4	0b RW	Completion Timeout Disable (CTD): When set to 1b, this bit disables the Completion Timeout mechanism. This field is required for all devices that support the Completion Timeout Disable Capability. Software is permitted to set or clear this bit at any time. When set, the Completion Timeout detection mechanism is disabled. If there are outstanding requests when the bit is cleared, it is permitted but not required for hardware to apply the completion timeout mechanism to the outstanding requests. If this is done, it is permitted to base the start time for each request on either the time this bit was cleared or the time each request was issued.
3:0	0h RW	Completion Timeout Value (CTV): In Devices that support Completion Timeout programmability, this field allows system software to modify the Completion Timeout value. This field is applicable to Root Ports, Endpoints that issue requests on their own behalf, and PCI Express to PCI/PCI-X Bridges that take ownership of requests issued on PCI Express. For all other devices this field is reserved and must be hardwired to 0000b. A Device that does not support this optional capability must hardwire this field to 0000b and is required to implement a timeout value in the range 50us to 50ms. Devices that support Completion Timeout programmability must support the values given below corresponding to the programmability ranges indicated in the Completion Timeout Values Supported field. The root port targeted configurable ranges are listed below, along with the range allowed by the PCI Express 2.0 specification. Defined encodings: 0000b Default range: 40-50ms (spec range 50us to 50ms) Values available if Range B (10ms to 250ms) programmability range is supported: 0101b 40-50ms (spec range is 16ms to 55ms) 0110b 160-170ms (spec range is 65ms to 210ms) Values available if Range C (250ms to 4s) programmability range is supported: 1001b 400-500ms (spec range is 260ms to 900ms) 1010b 1.6-1.7s (spec range is 1s to 3.5s) Values not defined above are Reserved. Software is permitted to change the value in this field at any time. For requests already pending when the Completion Timeout Value is changed, hardware is permitted to use either the new or the old value for the outstanding requests, and is permitted to base the start time for each request either when this value was changed or when each request was issued.

31:17	0000h RO	Reserved (RSVD): Reserved
16	0b RO/V	Current De-emphasis Level (CDL) : When the Link is operating at 5 GT/s speed, this bit reflects the level of de-emphasis. Encodings: 1b -3.5 dB 0b -6 dB The value in this bit is undefined when the Link is operating at 2.5 GT/s speed.
15:13	000b RO	Reserved (RSVD_1): Reserved
12	0b RW/P	Compliance De-emphasis (CD) : This bit sets the de-emphasis level in Polling.Compliance state if the entry occurred due to the Enter Compliance bit being 1b. Encodings: 1b-3.5 dB 0b-6 dB When the Link is operating at 2.5 GT/s, the setting of this bit has no effect. The default value of this bit is 0b. This bit is intended for debug, compliance testing purposes. System firmware and software is allowed to modify this bit only during debug or compliance testing.
11	0b RW/P	Compliance SOS (CSOS) : When set to 1b, the LTSSM is required to send SKP Ordered Sets periodically in between the (modified) compliance patterns. The default value of this bit is 0b.

Bit Range	Default & Access	Description
10	0b RW/P	Enter Modified Compliance (EMC): When this bit is set to 1b, the device transmits Modified Compliance Pattern if the LTSSM enters Polling.Compliance substate. Default value of this bit is 0b. This register is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this register only during debug or compliance testing. In all other cases, the system must ensure that this register is set to the default value.
9:7	000b RW/P	Transmit Margin (TM): This field controls the value of the nondeemphasized voltage level at the Transmitter pins. This field is reset to 000b on entry to the LTSSM Polling.Configuration substate (see PCI Express Chapter 4 for details of how the Transmitter voltage level is determined in various states). Encodings: 000b Normal operating range 001b 800-1200 mV for full swing and 400-700 mV for half-swing 010b - (n-1) Values must be monotonic with a non-zero slope. The value of n must be greater than 3 and less than 7. At least two of these must be below the normal operating range of n : 200-400 mV for full-swing and 100-200 mV for half-swing n - 111b reserved For a Multi-Function device associated with an Upstream Port, the field in Function 0 is of type RWS, and only Function 0 controls the component's Link behavior. In all other Functions of that device, this field is of type RsvdP. Default value of this field is 000b. Components that support only the 2.5 GT/s speed are permitted to hardwire this bit to 000b. This register is intended for debug, compliance testing purposes only. System firmware and software is allowed to modify this register only during debug or compliance testing. In all other cases, the system must ensure that this register is set to the default value.
6	0b RW/P	Selectable De-emphasis (SD): When the Link is operating at 5.0 GT/s speed, this bit selects the level of de-emphasis for an Upstream component. Encodings: 1b -3.5 dB 0b -6 dB When the Link is operating at 2.5 GT/s speed, the setting of this bit has no effect.
5	0b RO	Hardware Autonomous Speed Disable (HASD): Reserved. This port cannot autonomously change speeds.
4	0b RW/P	Enter Compliance (EC): Software is permitted to force a Link to enter Compliance mode at the speed indicated in the Target Link Speed field by setting this bit to 1b in both components on a Link and then initiating a hot reset on the Link. Default value of this bit following Fundamental Reset is 0b.
3:0	0h RW/P	Target Link Speed (TLS): This field sets an upper limit on Link operational speed by restricting the values advertised by the upstream component in its training sequences. For root port, the allowed value is: 0001b 2.5 GT/s Target Link Speed 0010b 5.0 GT/s and 2.5GT/s Link speeds supported If a value is written to this field that does not correspond to a speed included in the Supported Link Speeds field, the result is undefined. The default value of this field is the highest Link speed supported by the component (as reported in the Supported Link Speeds field of the Link Capabilities register).

Upon transition from D3hot to D0 Initialized state, no additional operating system intervention is required to preserve Configuration Context beyond writing the Power State bits. When clear, devices do perform an internal reset upon transitioning from D3hot to D0 via software control of the Power State bits. Configuration Context is lost when performing the soft reset. Upon transition from D3hot to D0 state, full reinitialization sequence is needed to return the device to D0 Initialized. Regardless of this bit, devices that transition from D3hot to D0 by a system or bus segment reset will return to the device state D0 Uninitialized with only PME context preserved if PME is supported and enabled.

Type 1 configuration cycles are also not accepted. Interrupts are not required to be blocked as software will disable interrupts prior to placing the port into D3HOT. If software attempts to write a '10' or '01' to these bits, the write will be ignored.

27:24	0h RO/V	Dot portion of Process ID (DPID): The value of this field is SoC specific. Example: Process/Dot (PD) is 1265.8. Indicates the dot as .8.
23:16	00h RO/V	Stepping Identifier (SID): This field is incremented for each stepping of the part. Note that this field can be used by software to differentiate steppings when the Revision ID may not change. A single Manufacturing Stepping ID can be implemented that is readable from all functions in the chip because all of them are incremented in lock-step.
15:8	0Fh RO	Manufacturing Identifier (MID): 0Fh = Intel
7:0	00h RO/V	Process/Dot (PD): Indicates the current process. The value of this field is SoC specific. Example: Process/Dot (PD) is 1265.8. Indicates the Process (1265).

pcs_dword2: [Port: 0xA6] + (200h + 8h)

Op Codes:

0h - Read, 1h - Write

Default: 00000000h

Bit Range	Default & Access	Description
4	0h RW	cri_forcebankhit : Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	cri_kalignmode_1_0 : KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	cri_skpprocdis : SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	cri_elasticbuffer_maskdis : Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

Bit Range	Default & Access	Description
31	0h RW	cri_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cri_dfx_prbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cri_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cri_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cri_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cri_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the Dfx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.
7:0	63h RW	cri_dfx_patbuf_15_8: Pattern Buffer Storage See cri_dfx_patbuf[7:0] description.

Bit Range	Default & Access	Description
31:24	X RO	dfx_cri_errcnt_7_0 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERASET.
23:16	X RO	dfx_cri_errcnt_15_8 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERASET.
15	X RO	i_rxcaldone : RX Calibration Cycles Complete Indicator
14	X RO	dfx_cri_lcemgnerr : Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx uppartition during Margin Mode to determine when the eye width has closed.
13	X RO	cri_dfx_patgen2active : Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress.
12	X RO	dfx_cri_patbufallfail : Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occurred during training.
11	X RO	dfx_cri_patchkactive : Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS).
10	X RO	dfx_cri_patgenactive : Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS).
9	X RO	dfx_cri_lctraindone : Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator.
8	X RO	dfx_cri_lctrainactive : Local Compare Engine Training Active status indicator Indicates that the Pattern Checker training is in progress (either Pattern Buffer or PRBS).
7	0h RW	reserved501 : reserved
6	0h RW	cri_dfx_patgen2en : Pattern Generator 2 Enable In a lane with two Tx paths, this enables the second Pattern Generator. The DFXPATGENEN will enable the first Pattern Generator. 0 : Disable second Pattern Generator (default) 1 : Enable second Pattern Generator
5:4	0h RW	cri_dfx_maxerrcnt_1_0 : Maximum Error Count Selectable maximum value that the DFXERRCNT can reach before the Local Compare Engine is automatically stopped. 00 : 2^{16} (default) 01 : 2^{10} 10 : 2^8 11 : 2^4
3:0	9h RW	cri_dfx_prbstraincnt_3_0 : PRBS Training Count The number of consecutive cycles that the Pattern Checker's PRBS must be error free before it is considered synchronized. Default is 9.

26	0h RW	i_rxsqfsm_timersel: Squelch FSM Timer Select 0 - Selects 25Mhz values for squelch timer and shunt pulse generation . 1 - Selects 100Mhz values for squelch timer and shunt pulse generation. This register is applicable to synchronous squelch startup mode.
25	0h RW	i_rxsq_asyncmode_h: Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

31:28	0h RW	reg_rxpwrfsm_pibiasoff_delay_3_0 : Override value for delay (in 2ns increments) between deassertion of opianclkbufen and opibiasen
27:24	0h RW	cri_sqdbexittimer_override_3_0 : Rx squelch exit debounce timer
23:18	0h RW	cri_sqdbentrytimer_override_5_0 : Rx squelch entry debounce timer
17:16	0h RW	reg_rxdrcgtsqsel_1_0 : Squelch output select
15	0h RW	cri_reut_SlaveSideDataCheckingEn : Enable REUT slave side checking while in loopback slave
14	0h RW	cri_sqdbtimer_ovren : Squelch debounce timer override enable
13	0h RW	cri_rxpwrfsm_timer_ovren : Rx power management fsm timer override enable
12	0h RW	reg_rxidle : Chicken bit to override i_rxidle from controller and keep Rx in P0 or P0s
11	0h RW	cri_rxrawdata_sel : When asserted bypass K-align, 10b/8b decoder and Elastic buffer
10	0h RW	cri_dynkalign_eco3302703_mode : Kalign Mode Override Value When cri_dynkalign_eco3302703_ovren is set, this value selects kalignmode 0 - use register bits cri_kalignmode[1:0] to select kalignmode 1 - select the 4 COM kalign mode'
9	0h RW	cri_dynkalign_eco3302703_ovren : Kalign Mode Override Enable Overrides kalign mode select pin, allowing config bit kalignmode_override_val to select kalignmode.
8	0h RW	reg_rxpwrfsm_pibiasoff_ovrride : When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0]
7	0h RW	cri_reset_kalignlck : When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc.
6	0h RW	cri_ebptrrst : Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons.
5	0h RW	cri_comdispfix : Chicken bit to force disparity in dynamic K-align mode

Bit Range	Default & Access	Description
4	0h RW	cri_forcebankhit : Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	cri_kalignmode_1_0 : KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	cri_skpprocdis : SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	cri_elasticbuffer_maskdis : Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

Access Method

Bit Range	Default & Access	Description
31	0h RW	cri_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cri_dfx_prbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cri_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cri_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cri_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cri_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the Dfx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCERESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

25	0h RW	i_rxsq_asyncmode_h: Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

27:26	3h RW	oscaledcompmethod_1_0 : Used to define if we use scaling of the compensation values or not. The purpose is to have gen dependant scaling / non-scaling When '00' - don't used scaled comp When '01' - if fast-clock is not divided (gen2?) don't scale-comp otherwise (gen1?) use scaled-comp When '10' - if fast-clock is not divided or divided by 2 (gen2?) don't scale-comp otherwise (gen1?) use scaled-comp (will probably be down-scaling amount of slices) When '11' - if fast-clock is not divided (gen2?) use scaled-comp otherwise (gen1?) don't use scaled-comp (will probably be up-scaling amount of slices)
25	0h RW	odeemswinggenmethod : Used to select scaling of -3.5dB deemphasis either ow2tapgen1deemph3p5[7:0] or ow2tapgen2deemph3p5[7:0] When '0' - if fast-clock is not divided use gen2 otherwise use gen1 When '1' - if fast-clock is not divided or divided by 2 use gen2 otherwise use gen1
24	0h RW	odownscaleampmethod : when margin='001', this bit with dataratefit are used to select between margin000 (for gen2) and margin101 (for gen1) when '0' - if fast-clock is not divided use margin000 (gen2) otherwise use margin101 (gen1) when '1' - if fast-clock is not divided or divided by 2 use margin000 (gen2) otherwise use margin101 (gen1)
23:16	78h RW	omargin101_7_0 : factor (X/128) of slices to use in main-R1 for full swing level. Used for ~1V p2p to be used in Gen1 mode (Gen1/Gen2 depends on dataratefit and downscaleamp register)
15:8	20h RW	omargin100_7_0 : factor (X/128) of slices to use in main-R1 for full swing level. Used for ~1/4Vp2p
7:0	40h RW	omargin011_7_0 : factor (X/128) of slices to use in main-R1 for full swing level. Used for ~1/2Vp2p

23.11.5 PCS_DWORD4 (pcs_dword4)—Offset 10h

Access Method

Bit Range	Default & Access	Description
31	0h RW	cri_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cri_dfx_prbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cri_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cri_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cri_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cri_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the Dfx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

Bit Range	Default & Access	Description
31:24	X RO	dfx_cri_errcnt_7_0 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
23:16	X RO	dfx_cri_errcnt_15_8 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERESSET.
15	X RO	i_rxcaldone : RX Calibration Cycles Complete Indicator
14	X RO	dfx_cri_lcemgnerr : Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx uppartition during Margin Mode to determine when the eye width has closed.
13	X RO	cri_dfx_patgen2active : Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress.
12	X RO	dfx_cri_patbufallfail : Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occurred during training.
11	X RO	dfx_cri_patchkactive : Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS).
10	X RO	dfx_cri_patgenactive : Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS).
9	X RO	dfx_cri_lctraindone : Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator.

26	0h RW	i_rxsqfsm_timersel : Squelch FSM Timer Select 0 - Selects 25Mhz values for squelch timer and shunt pulse generation . 1 - Selects 100Mhz values for squelch timer and shunt pulse generation. This register is applicable to synchronous squelch startup mode.
25	0h RW	i_rxsq_asyncmode_h : Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.
24	1h RW	i_rxsquelchstby_h : Fast Squelch Enable Mode Bit to keep the IREF (ivrefen) on during P2 and reduce squelch startup time.

8	0h RW	reg_rxpwrfsm_pibiasoff_ovrride : When asserted selects reg_rxpwrfsm_pibiasoff_delay[3:0]
7	0h RW	cri_reset_kalignlck : When asserted resets Kalign lock indication and Kalign is performed again. The conditions when this would assert includes and is not restricted to any power management states (L0s, L1) or polling quiet states etc.
6	0h RW	cri_ebptrrst : Global broadcast to all lanes that the Elastic Buffer pointers should be reset. This is a pulse and will be generated when we need to reset the pointers because of collision or various other reasons.
5	0h RW	cri_comdispfix : Chicken bit to force disparity in dynamic K-align mode

Bit Range	Default & Access	Description
4	0h RW	cri_forcebankhit : Chicken bit to enable data appear on NOA post k-align lock although k-align block is not achieving lock. This is only for NOA observeability and not for other purpose
3:2	0h RW	cri_kalignmode_1_0 : KALIGN Mode Select 00 = dynamic kalign all the time. Accounts for bit slips on incoming stream which can cause symbol to be detected on different bank 10 = dynamic kalign up to L0 x1 = static kalign (same as GDG). Assumes symbol always detected on same data bank
1	0h RW	cri_skpprocdis : SKIP Ordered-Set Processing Disable When this configuration bit is asserted, then SKIP ordered=sets will be ignored (in EB block). Used in Elastic buffer block. 0 = Normal operation. SKIP ordered=sets will be processed by the Elastic Buffer 1 = SKIP processing disabled.
0	0h RW	cri_elasticbuffer_maskdis : Config bit (chicken bit) to disable the masking logic after elec idle ordered set is seen

23.13.5 PCS_DWORD4 (pcs_dword4)—Offset 10h

Access Method

Bit Range	Default & Access	Description
31	0h RW	cri_dfx_patbuftrain: Pattern Buffer Manual Training When DFXPATBUFTRAINOVR and DFXLCESTART are asserted, this manually controls whether the Pattern Buffers are in training or have completed training. 0 : Send training patterns (default) 1 : Send contents of DFXPATBUF
30:28	0h RW	cri_dfx_prbspoly_2_0: PRBS Polynomial Select the polynomial to be used by the PRBS in the Pattern Generator and Pattern Checker. PRBS support 10b or 8b, which is indicated by the msb. 000 - $x^{16} + x^5 + x^4 + x^3 + 1$ (USB3/PCIe Scrambler) (8b) 001 - $x^{16} + x^{15} + x^{13} + x^4 + 1$ (SATA scrambler) (8b) 010 - $x^{31} + x^{28} + 1$ (8b) 011 - $x^7 + x^6 + 1$ (8b) 100 - $x^{15} + x^{14} + 1$ (10b) 101 - $x^{23} + x^{18} + 1$ (10b) 110 - $x^{31} + x^{28} + 1$ (10b) 111 - $x^7 + x^6 + 1$ (10b)
27:26	0h RW	cri_dfx_patbufsize_1_0: Pattern Buffer Size Select the size of the Pattern Buffer to use. The MSB will always be bit 79. The LSB will depend on this select and the DFXLCEDATAWIDTH (10b or 8b mode). 00 : full 80b buffer (Default) 01 : 70b (while in 10b mode), 56b (while in 8b mode) 10 : 40b (while in 10b mode), 32b (while in 8b mode) 11 : 10b (while in 10b mode), 8b (while in 8b mode)
25	0h RW	cri_dfx_patbufloop: Pattern Buffer Looping Enable Enables looping of the Pattern Buffer. By default, the contents of Pattern Buffer will be used once and stop. Alternatively, the Pattern Buffer will continue to loop until the DFXLCESTART is de-asserted. 0 : Run Pattern Buffer only once (default) 1 : Loop Pattern Buffer until stopped
24	0h RW	cri_dfx_patbufdwidth: Pattern Buffer Data Width Selects between 10 bit or 8 bit data width for the Pattern Buffer. Determines where in the Tx/Rx path the data is inserted/retrieved. 0 : 10b (default) 1 : 8b
23	0h RW	cri_dfx_patbuftrainovr: Pattern Buffer Training Override Enables manual training of the Pattern Buffer instead of the automated coordination between the Pattern Checker and Pattern Generator. When asserted, the DFXPATBUFTRAIN bit will be used to force when training is active and when it is complete. 0 : Automatic Training (default) 1 : Enable Manual Training
22	0h RW	cri_dfx_marginmode: Margin mode Overrides standard setup configurations for use with Eye Width Margining. 0 : Standard Mode (default) 1 : Margin Mode enabled
21	0h RW	cri_dfx_chk_sel: Pattern Checker 8b10b Select This determines where Rx data is compared, either in the 10-bit domain before decode or after 10b-8b decoding. 0: 10b domain 1: 8b domain
20	0h RW	cri_dfx_patchken: Pattern Checker Enable 0 : Disable Pattern Checker (default) 1 : Enable Pattern Checker
19	0h RW	cri_dfx_patgenen: Pattern Generator Enable This will activate the Dfx bypass muxes in the PCS Tx path. 0 : Disable Pattern Generator (default) 1 : Enable Pattern Generator
18	0h RW	cri_dfx_clrerrcnt: Clear Error Counter Resets the Pattern Checker's error counter. 0 : Error Counter allowed to run (default) 1 : Error Counter held in reset
17	0h RW	cri_dfx_lcereset: Local Compare Engine Reset Resets all components of the Local Compare Engine in both the Pattern Generator and the Pattern Checker. 0 : LCE not in reset (default) 1 : LCE in reset
16	0h RW	cri_dfx_lcestart: Local Compare Engine Start Controls the starting and stopping of the LCE. Allows for simultaneous or independent start across lanes. Once stopped, a DFXLCESET is usually required. 0 : LCE stopped (default) 1 : LCE running
15:8	3Eh RW	cri_dfx_patbuf_7_0: Pattern Buffer Storage In 10b mode, the buffer is read as eight 10b chunks. The first 10 bits should not equal the Comma Symbol: '0011111010' (or its inversion '1100000101'). In 8b mode, the buffer is read as eight 10b chunks, where the 10th bit is unused and the 9th bit is the K-bit indicator. The first 10 bits should not equal the Comma Symbol: 'xx10111100'. DFXPATBUF[78] should not = '1'.

Bit Range	Default & Access	Description
31:24	X RO	dfx_cri_errcnt_7_0 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERASET.
23:16	X RO	dfx_cri_errcnt_15_8 : Error Counter Tracks how many bit errors the Pattern Checker has detected. Can be cleared using DFXCLRERRCNT or DFXLCERASET.
15	X RO	i_rxcaldone : RX Calibration Cycles Complete Indicator
14	X RO	dfx_cri_lcemgnerr : Local Compare Engine Margin Error Indicates that the error counter has reached its max value. This can be used by the Rx uppartition during Margin Mode to determine when the eye width has closed.
13	X RO	cri_dfx_patgen2active : Pattern Generator 2 Active status indicator In a lane with two Tx paths, this indicates that the second Pattern Generator is in progress. The DFXPATGENACTIVE will only indicate that the first Pattern Generator is in progress.
12	X RO	dfx_cri_patbufallfail : Pattern Buffer All Fail status indicator Indicates that there has not been a single matching Pattern Buffer pattern. This could signify that an error occurred during training.
11	X RO	dfx_cri_patchkactive : Pattern Checker Active status indicator Indicates that the Pattern Checker is in progress (either Pattern Buffer or PRBS).
10	X RO	dfx_cri_patgenactive : Pattern Generator Active status indicator Indicates that the Pattern Generator is in progress (either Pattern Buffer or PRBS).
9	X RO	dfx_cri_lctraindone : Local Compare Engine Training Done status indicator Indicates that the Pattern Checker training is completed (either Pattern Buffer or PRBS). The Pattern Checker is now synchronized to the Pattern Generator.
8	X RO	dfx_cri_lctrainactive : Local Compare Engine Training Active status indicator Indicates that the Pattern Checker training is in progress (either Pattern Buffer or PRBS).
7	0h RW	reserved501 : reserved
6	0h RW	cri_dfx_patgen2en : Pattern Generator 2 Enable In a lane with two Tx paths, this enables the second Pattern Generator. The DFXPATGENEN will enable the first Pattern Generator. 0 : Disable second Pattern Generator (default) 1 : Enable second Pattern Generator
5:4	0h RW	cri_dfx_maxerrcnt_1_0 : Maximum Error Count Selectable maximum value that the DFXERRCNT can reach before the Local Compare Engine is automatically stopped. 00 : 2 ¹⁶ (default) 01 : 2 ¹⁰ 10 : 2 ⁸ 11 : 2 ⁴
3:0	9h RW	cri_dfx_prbstraincnt_3_0 : PRBS Training Count The number of consecutive cycles that the Pattern Checker's PRBS must be error free before it is considered synchronized. Default is 9.

26	0h RW	i_rxsqfsm_timersel : Squelch FSM Timer Select 0 - Selects 25Mhz values for squelch timer and shunt pulse generation . 1 - Selects 100Mhz values for squelch timer and shunt pulse generation. This register is applicable to synchronous squelch startup mode.
25	0h RW	i_rxsq_asyncmode_h : Squelch Async Startup Mode This squelch startup mode is power state independent. When enabled, the squelchen signal sent to Modphy will asynchronously enable the squelch detector circuit. Once enabled, the squelch detector circuit will asynchronously send an unfiltered/unqualified squelch indication signal out of Modphy. The squelch indication signal will initially be unstable, so it is up to the consumer of this signal to filter/qualify it accordingly. The asynchronous squelch startup mode is beneficial because it significantly reduces the squelch startup latency. This decrease in latency does come at the cost of slightly higher power when squelch is not enabled as the IREF and Squelch Keeper circuits must remain enabled. When disabled, the squelch startup sequence is synchronous in nature and the squelch indication signal sent out of Modphy is stable/filtered.

16	0h RW	oirefcurmonsel : IREF Current Monitor Select Enables current mirror from the IREF block to the 'shared' analog monitor port.
15	0h RW	lrcdisable : LRC Disable This bit disables the LRC. Any token received is passed to the next lane.
14:12	0h RW	reserved521 : reserved
11	0h RW	lrc_rdy_pulsegen : LRC Ready PulseGen Generates a pulse 1 cal_clk cycle wide on the lrc_rdy signal to all four targets; does not recompute local Rcomp code. Values in DWD 0x14 (*rccodes[7:0]) will be latched into targets. User must clear this bit before generating another pulse. Note: User should disable PM and PER. FSM can take control and codes can be overridden.

Bit Range	Default & Access	Description
31:24	80h RW	rxvgarccode_7_0 : Rx VGA Rcomp Codes These bits are the final binary code used by the Rx VGA. This block only uses the X upper MSBs of this value. Writing to this register will override the rcomp code to the Rx VGA. An LRC Ready pulse must be generated to the Rx VGA target for this value to take effect. [7:n] - compensation code sent to Iref [n-1:0] - remaining LSBs from scaling and offset calculation
23:16	80h RW	rxtermrccode_7_0 : Rx Termination Rcomp Codes These bits are the final binary code used by the Rx termination. This block only uses the 7 upper MSBs of this value. Writing to this register will override the rcomp code to Rxterm. An LRC Ready pulse must be generated to the Rxterm target for this value to take effect. [7:1] - compensation code sent to Rxterm [0] - remaining LSB from scaling and offset calculation
15:8	80h RW	txrccode_7_0 : Tx Rcomp Codes These bits are the final binary code used by the Tx. This block only uses the 7 upper MSBs of this value. Writing to this register will override the rcomp code to the Tx. An LRC Ready pulse must be generated to the Tx target for this value to take effect. [7:1] - compensation code sent to Tx [0] - remaining LSB from scaling and offset calculation
7:0	80h RW	irefrccode_7_0 : Iref Rcomp Codes These bits are the final binary code used by the Iref block. This block only uses the 6 upper MSBs of this value. Writing to this register will override the rcomp code to the Iref block. An LRC Ready pulse must be generated to the Iref target for this value to take effect. [7:2] - compensation code sent to Iref [1:0] - remaining LSBs from scaling and offset calculation

16	1h RW	cri_lanereset_clkgatectl : 1: The assertion of lane reset will have the effect of gating the susclk and de-asserting the internal laneclkreq. This mode is only valid when the data lane dynamic clock gating mode is set to a non-zero value (i.e. 01, 10, and 11). 0: The assertion of lane reset will have no effect on the gating of susclk and state of the internal laneclkreq signal.
15	1h RW	cri_lanereqforce : Controls whether the internal laneclkreq will be forced to 1 or 0 when cfg_data_dynclkgate_mode is set to 00 or 10. 1: force laneclkreq high 0: force laneclkreq low. This mode will likely be used when one of the lanes is disabled while other lanes in the family are enabled. In this case the internal laneclkreq of the disabled lane should be de-asserted (not influencing the clk gating decision)
14:10	10h RW	cri_susclkdisable_delay_4_0 : This register will control the number of cycles to delay the susclk enable de-assertion, in addition to the de-assertion of the laneclkreq signal sent out of the datalane. 9:8	0h RW	cri_data_dynclkgate_mode_1_0 : Controls the dynamic clock gating behavior in the data lane. 00 - susclk gating and laneclkreq disabled (Forced to configured value). In this mode the susclk will not be gated under any circumstances and the laneclkreq sent out of the lane will be forced to a programmed value (can be forced high or low) 01 - susclk gating disabled, laneclkreq enabled . In this mode the susclk will not be gated under any circumstances. The laneclkreq sent out of the data lane will toggle based on whether the lane power state, susclk need and the previous lane's laneclkreq signal. 10 - susclk gating enabled, laneclkreq disabled (forced to configured value) - In this mode the susclk will be gated during P2/Slumber when there are no requests to change the TX common mode. The laneclkreq sent out of the lane will be forced to a programmed value (can be forced high or low) 11 - susclk gating and laneclkreq enabled - In this mode the susclk will be gated during P2/Slumber when there are no requests to change the TX common mode. The laneclkreq sent out of the data lane will toggle based on the lane power state, susclk need and the previous lane's laneclkreq signal.

23.14.12 TX_DWORD11 (tx_dword11)—Offset 2Ch

Access Method

Type: Message Bus Register
(Size: 32 bits)

tx_dword11: [Port: 0xA6] + (880h + 2Ch)

Op Codes:

0h - Read, 1h - Write

Default: 00001000h

Bit Range	Default & Access	Description
29:27	0h RW	ofrcdataratefit_2_0 : Forces TX data rate 3'b0XX - don't force a value. get it from the I/F pin 3'b100 - no divide (2UIs per clock cyc) 3'b101 - divide by 2 3'b110 - divide by 4 3'b111 - divide by 8 - used also for bypassing with other clocks
26	0h RW	odistxfelbpin : when asserted - disables the i_txfelben pin at the interface and force it 0. (needed in case the pin is asserted in KX or sata1 mode)
25	0h RW	otxcikampbypsn : 0': Normal operation '1': Enable of the passgate connected from the analog clock N to the control of the DC correction cell. The feedback OTA is disabled.
24	0h RW	otxcikampbypsp : 0': Normal operation '1': Enable of the passgate connected from the analog clock P to the control of the DC correction cell. The feedback OTA is disabled.
23	0h RO	reserved539 : reserved
22	0h RW	odfxanamuxen : Enables analog signals probing mux out. When enabled the Vref of Tx-detect-Rx circuit is observed. Note that only one lane is allowed to have the analog mux enabled to avoid collisions.
21:20	0h RW	odfxanamuxsel_1_0 : selects analog signal to be sent to analog port in common lane. This bus has no affect at all currently because there is only one analog signal for observation which is observed by odfxanamuxen
19:18	0h RW	obs_tx_gated_supply_1_0 : Monitor gated vcc supply to Tx upar

24 Serial I/O (SIO) Overview

The Serial I/O (SIO) is a collection of hardware blocks that implement simple but key serial I/O interfaces for platform usage. These hardware blocks include:

- SIO - I²C Interface
- SIO - High Speed UART
- SIO - Serial Peripheral Interface (SPI)
- SIO - Pulse Width Modulation (PWM)

24.1 Serial I/O (SIO) Register Map

Refer to [Chapter 3, "Register Access Methods"](#) and [Chapter 4, "Mapping Address Spaces"](#) for additional information.

24.2.1 Device ID and Vendor ID Register (DEVVENDID)—Offset 0h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 0h

Default: 00008086h

DEVICEID				VENDORID				

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Device ID (DEVICEID): Device ID identifies the particular AHB device. This is tied to a strap at the top level.
15:0	8086h RO	Vendor ID (VENDORID): Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

24.2.2 Status and Command (STATUSCOMMAND)—Offset 4h

Access Method

Bit Range	Default & Access	Field Name (ID): Description
1	0h RW	Memory Space Enable (MSE) : This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6 : Reserved.

24.2.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 8h

Default: 00000000h

CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES) : The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID) : Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

24.2.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + Ch

Reserved0		MULFNDEV	HEADERTYPE			LATTIMER		CACHELINE_SIZE	

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address Register 1 (BASEADDR1): BAR1 of the LPIO device.
11:4	00h RO	SIZEINDICATOR1: Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1): Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1): 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1): 0. Indicates this BAR is present in the memory space.

24.2.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.

Bit Range	Default & Access	Field Name (ID): Description
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

24.2.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0: Reserved.

Bit Range	Default & Access	Field Name (ID): Description
7:0	00h RO	Capabilities Pointer (CAPPTR_POWER) : Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

24.2.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 3Ch

Default: 00000100h

MAX_LAT				MIN_GNT				Reserved0		INTPIN		INTLINE	

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0 : Reserved.
11:8	1h RO	Interrupt Pin (INTPIN) : Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE) : Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

24.2.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + 80h

Default: 00030001h

31	28	24	20	16	12	8	4	0

PMESUPPORT				Reserved0				VERSION		NXTCAP		POWER_CAP	

Bit Range	Default & Access	Field Name (ID): Description
3	1h RO	No_Soft_Reset (NO_SOFT_RESET) : This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3 : Reserved.
1:0	0h RW	Power State (POWERSTATE) : This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

24.2.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:0] + F8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Manufacturer ID (MANID) : This register is brought out as straps to the top level.

24.3.1 Source Address Register for Channel 0 - Low (SAR0_LO)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current AHB transfer.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	0h RW	Current Source Address of DMA Transfer (SAR): Updated after each source transfer. The SINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer.

24.3.2 Source Address Register for Channel 0 - High (SAR0_HI)— Offset 4h

Refer to the description for register Source Address Register for Channel 0 - Low.

24.3.177 Interrupt Raw Status Registers - Low (RawTfr_LO)—Offset 2C0h

Interrupt events are stored in these Raw Interrupt Status registers before masking: RawBlock, RawDstTran, RawErr, RawSrcTran, and RawTfr. Each Raw Interrupt Status register has a bit allocated per channel; for example, RawTfr[2] is the Channel 2 raw transfer complete interrupt. Each bit in these registers is cleared by writing a 1 to the corresponding location in the ClearTfr, ClearBlock, ClearSrcTran, ClearDstTran, ClearErr registers.

24.3.199 Interrupt Mask Registers - Low (MaskBlock_LO)—Offset 318h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel; for example, MaskTfr[2] is the mask bit for the Channel 2 transfer complete interrupt.

24.3.237 DW_ahb_dmac Test Register - Low (DmaTestReg_LO)—Offset 3B0h

This register is used to put the AHB slave interface into test mode, during which the readback value of the writable registers match the value written, assuming the DW_ahb_dmac configuration has not optimized the same registers. In normal operation, the readback value of some registers is a function of the DW_ahb_dmac state, and does not match the value written.

24.3.246 DW_ahb_dmac Component Parameters Register 3 - High (DMA_COMP_PARAMS_3_HI)—Offset 3E4h

This is a constant read-only register that contains encoded information about the component parameter settings for Channel 1 and Channel 2. The reset value depends on coreConsultant parameter(s).

19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable (URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

24.4.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 8h

Default: 00000000h

31	28	24	20	16	12	8	4	0
0	0	0	0	0	0	0	0	0
CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

24.4.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + Ch

Default: 00800000h

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	1h RO	Multi Function Device (MULFNDEV): This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. <ul style="list-style-type: none"> 1 = multifunction device 0 = single function device
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

24.4.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	Size Indicator Read Only (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	Type (TYPE) : 00 indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE) : 0. Indicates this BAR is present in the memory space.

24.4.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 14h

Default: 00000000h

31	28	24	20	16	12	8	4	0	
0	0	0	0	0	0	0	0	0	
BASEADDR1				SIZEINDICATOR1			PREFETCHABLE1	TYPE1	MESSAGE_SPACE1

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address Register 1 (BASEADDR1) : BAR1 of the LPIO device.
11:4	00h RO	SIZEINDICATOR1 : Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1) : Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1) : 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1) : 0. Indicates this BAR is present in the memory space.

24.4.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

24.4.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 30h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

24.4.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 34h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0 : Reserved.
7:0	00h RO	Capabilities Pointer (CAPPTR_POWER) : Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

24.4.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 3Ch

Default: 00000100h

31	28	24	20	16	12	8	4	0

MAX_LAT				MIN_GNT				Reserved0		INTPIN		INTLINE	

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0 : Reserved.
11:8	1h RO	Interrupt Pin (INTPIN) : Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE) : Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

24.4.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + 80h

Bit Range	Default & Access	Field Name (ID): Description
15	0h RW/1C	PME Status (PMESTATUS): <ul style="list-style-type: none"> 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PME Enable (PMEENABLE): A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	No_Soft_Reset (NO_SOFT_RESET): This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	Power State (POWERSTATE): This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

24.4.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:0] + F8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Manufacturer ID (MANID): This register is brought out as straps to the top level.

24.5.177 Interrupt Raw Status Registers - Low (RawTfr_LO)—Offset 2C0h

Interrupt events are stored in these Raw Interrupt Status registers before masking: RawBlock, RawDstTran, RawErr, RawSrcTran, and RawTfr. Each Raw Interrupt Status register has a bit allocated per channel; for example, RawTfr[2] is the Channel 2 raw transfer complete interrupt. Each bit in these registers is cleared by writing a 1 to the corresponding location in the ClearTfr, ClearBlock, ClearSrcTran, ClearDstTran, ClearErr registers.

24.5.237 DW_ahb_dmac Test Register - Low (DmaTestReg_LO)—Offset 3B0h

This register is used to put the AHB slave interface into test mode, during which the readback value of the writable registers match the value written, assuming the DW_ahb_dmac configuration has not optimized the same registers. In normal operation, the readback value of some registers is a function of the DW_ahb_dmac state, and does not match the value written.

24.5.246 DW_ahb_dmac Component Parameters Register 3 - High (DMA_COMP_PARAMS_3_HI)—Offset 3E4h

This is a constant read-only register that contains encoded information about the component parameter settings for Channel 1 and Channel 2. The reset value depends on coreConsultant parameter(s).

25 SIO – Serial Peripheral Interface (SPI)

The Serial I/O implements one SPI controller that supports master mode.

Note: This SPI controller does not support platform firmware (BIOS). See the SPI controller in the PCU instead.

25.1 Signal Descriptions

Please see [Chapter 2, "Physical Interfaces"](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal's function

25.2 Features

The following is a list of SPI features:

- Single interrupt line
 - Could be assigned to interrupt PCI INT [A] or ACPISIO INT[1]
- Configurable frame format, clock polarity and clock phase
- supporting one SPI peripheral only
- Supports master mode only
- Receive and transit buffers are both 256x32bits
 - The receive buffer has only 1 water mark
 - The transmit buffer has 2 water marks
- Supports up to 15 Mbps

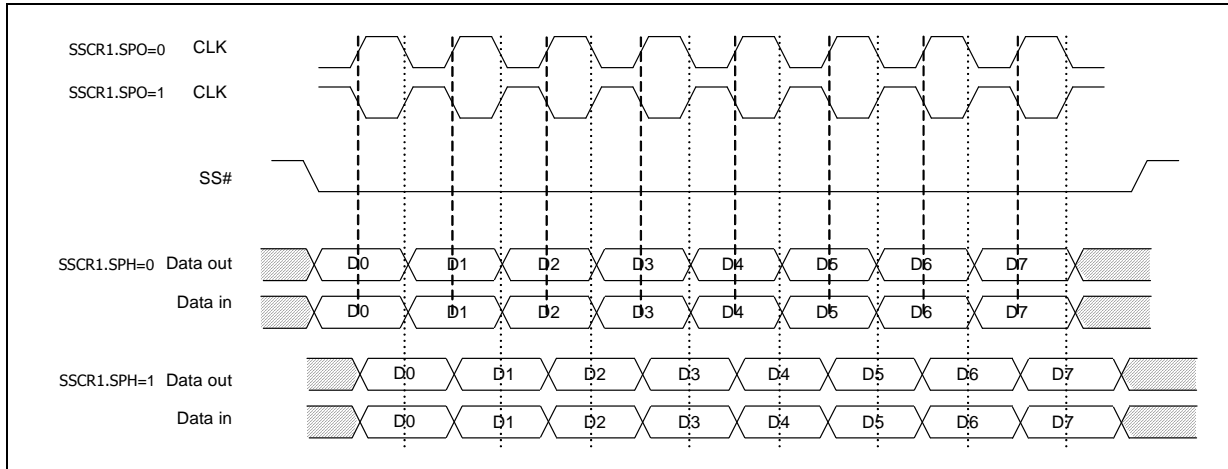

25.2.1 Clock Phase and Polarity

SPI clock phase and clock polarity overview.

- The SSCR1.SPO polarity setting bit determines whether the serial transfer occurs on the rising edge of the clock or the falling edge of the clock.
 - When SSCR1.SPO = 0, the inactive or idle state of SIO_SPI_CLK is low.
 - When SSCR1.SPO = 1, the inactive or idle state of SIO_SPI_CLK is high.
- The SSCR1.SPH phase setting bit selects the relationship of the serial clock with the slave select signal.
 - When SSCR1.SPH = 0, SIO_SPI_CLK is inactive until one cycle after the start of a frame and active until 1/2 cycle after the end of a frame.
 - When SSCR1.SPH = 1, SIO_SPI_CLK is inactive until 1/2 cycle after the start of a frame and active until one cycle after the end of a frame.

Below figure shows an 8-bit data transfer with different phase and polarity settings.

Figure 118. Clock Phase and Polarity

- In a single frame transfer, the SPI controller supports all four possible combinations for the serial clock phase and polarity.

25.2.2 Mode Numbers

The combinations of polarity and phases are referred to as modes which are commonly numbered according to the following convention, with SSCR1.SPO as the high order bit and SSCR1.SPH as the low order bit.

Table 254. SPI Modes

Mode	SSCR1.SPO	SSCR1.SPH
0	0	0
1	0	1
2	1	0
3	1	1

25.2.3 Frame Direction

The SSCR1.SFRMDIR bit is a read-write bit that determines whether the SSP is the master or slave with respect to driving the SSPSRM. When SSCR1.SFRMDIR=0, the SSP generates the SSPSRM internally, acts as the master and drives it. When SSCR1.SFRMDIR=1, the SSP acts as the slave and receives the SSPSRM signal from an external device. When the SSP is to be configured as a slave to the frame, the external device driving frame must wait until the SSSR.CSS bit is cleared after enabling the SSP before asserting frame (i.e. not external clock cycles are needed, the external device just needs to wait a certain amount of time before asserting frame). When the GPIO alternate function is selected for the SSP, this bit has precedence over the GPIO direction bit (i.e. if SFRMDIR=1, the GPIO is an input, and if SFRMDIR=0, then the pin is an output). Therefore, the SCLKDIR and SFRMDIR bits should be written to before

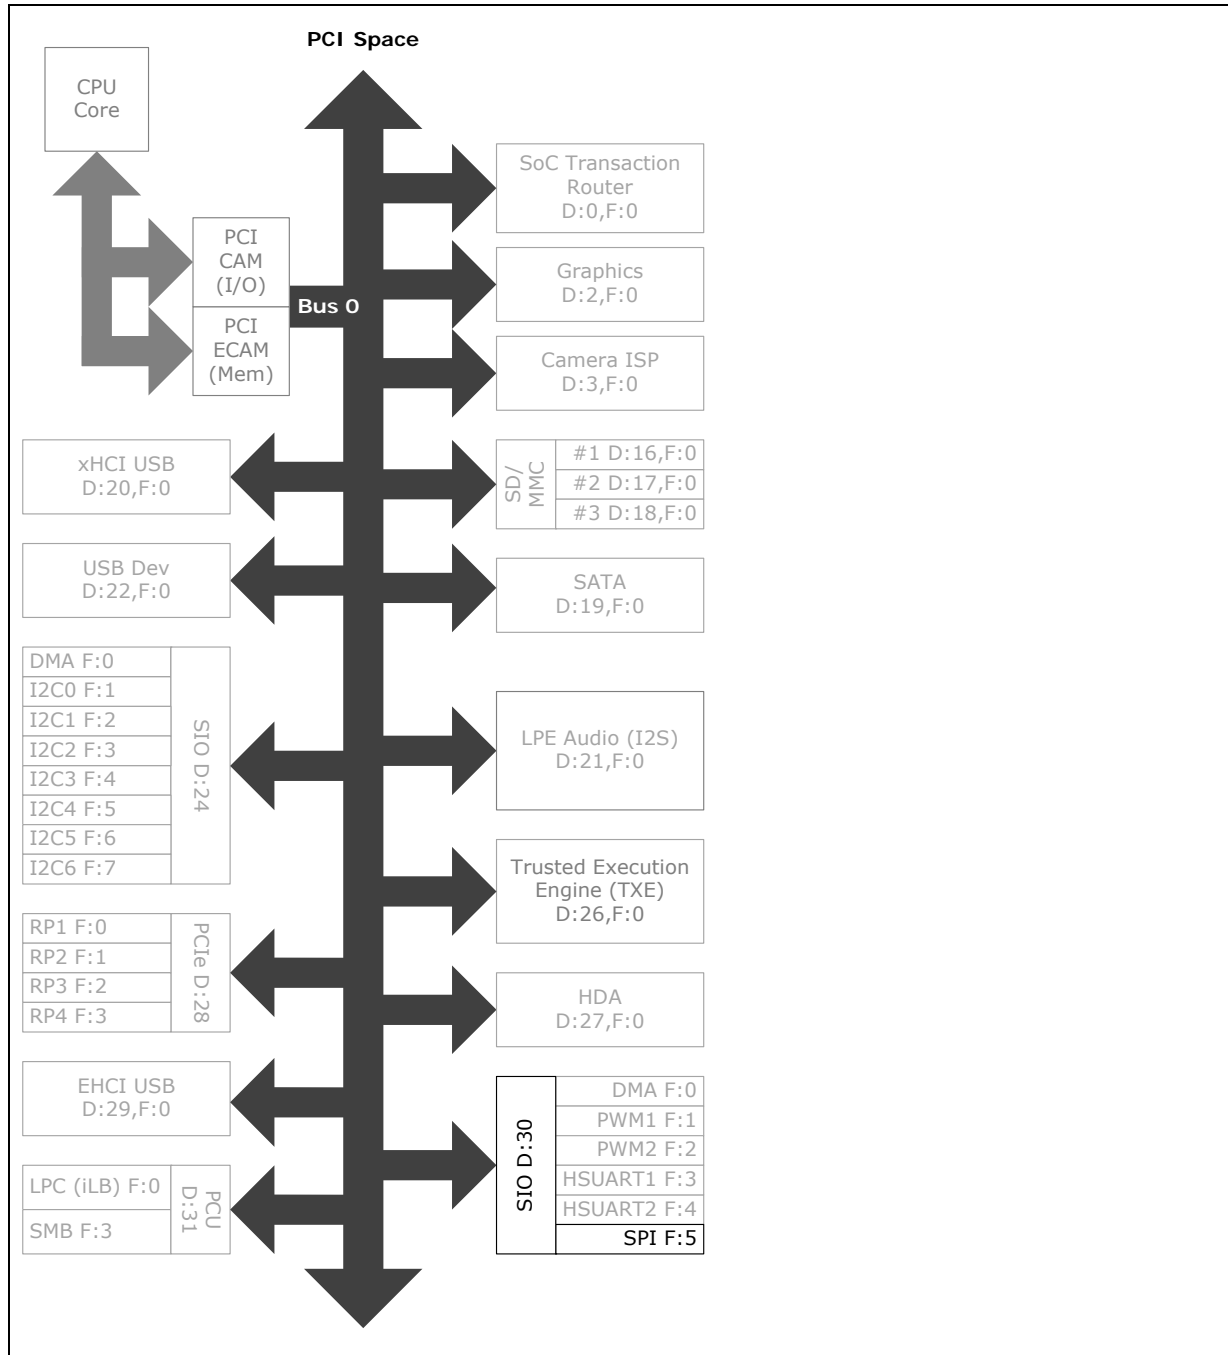

the GPIO direction bits (to prevent any possible contention of the SSPCLK or SSPSRM pins). Also, when the SCLKDIR bit is set, the SSCR0.NCS and SSCR0.ECS bits must be cleared.

31:8	000000h RO	Class Code (CLASS_CODES) : The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID) : Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

25.5.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

25.5.5 SSP Data (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

25.5.7 SSP Programmable Serial Protocol (SSPSP)—Offset 2Ch

The Enhanced SSP Programmable Protocol registers are read-write registers that contain eight fields that are used to program the various programmable serial-protocol parameters. When using PSP format in Network mode, the parameters SFRMDLY, STRTDLY, DMYSTP, DMYSTRT must be set to 0. Other parameters (such as FRMPOL, SCMODE, FSRT, SFRMDWDTH) are programmable. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

26 SIO - I²C Interface

The SoC supports 7 instances of I²C controller. Both 7-bit and 10-bit addressing modes are supported. These controllers operate in master mode only.

26.1 Signal Descriptions

I²C is a two-wire bus for inter-IC communication. Data and clock signals carry information between the connected devices. The following is the I²C Interface. The SoC supports 7 I²C interfaces for general purpose to control external devices. The I²C signals are muxed over GPIOs.

Please see [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 257. I²C[6:0] Signals

Signal Name	Direction Plat. Power	Description
SIO_I2C[6:0]_DATA	I/O V1P8S	I²C Serial Data <i>These signals are muxed and may be used by other functions.</i>
SIO_I2C[6:0]_CLK	I/O V1P8S	I²C Serial Clock <i>These signals are muxed and may be used by other functions.</i>

26.2 Features

26.2.1 I²C Protocol

The I²C bus is a two-wire serial interface, consisting of a serial data line and a serial clock. These wires carry information between the devices connected to the bus. Each device is recognized by a unique address and can operate as either a “transmitter” or “receiver,” depending on the function of the device. Devices are considered slaves when performing data transfers, as the SoC will always be a Master. A master is a device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. At that time, any device addressed is considered a slave.

- The SoC is always the I²C master; and it supports multi-master mode.
- The SoC can support clock stretching by slave devices.
- The SIO_I2Cx_DATA line is a bidirectional signal and changes only while the SIO_I2Cx_CLK line is low, except for STOP, START, and RESTART conditions.
- The output drivers are open-drain or open-collector to perform wire-AND functions on the bus.
- The maximum number of devices on the bus is limited by the maximum capacitance specification of 400 pF
- Refer to [Chapter 9, “Electrical Specifications”](#) for details.
- Data is transmitted in byte packages.

26.2.2 I²C Modes of Operation

The I²C module can operate in the following modes:

- Standard mode (with a bit rate up to 100 Kb/s)
- Fast mode (with a bit rate up to 400 Kb/s)
- Fast-mode Plus (Fm+, with a bit rate up to 1 Mb/s)
- High-speed mode (Hs-mode, with a bit rate up to 3.4 Mb/s)

Note: Higher speeds require tuning of the analog buffers. Please work with your BIOS vendor to incorporate.

The I²C can communicate with devices only using these modes as long as they are attached to the bus. Additionally, high speed mode, fast mode plus and fast mode devices are downward compatible.

- High-speed mode devices can communicate with fast mode and standard mode devices in a mixed speed bus system.
- Fast mode devices can communicate with standard mode devices in a 0–100 Kb/s I²C bus system.

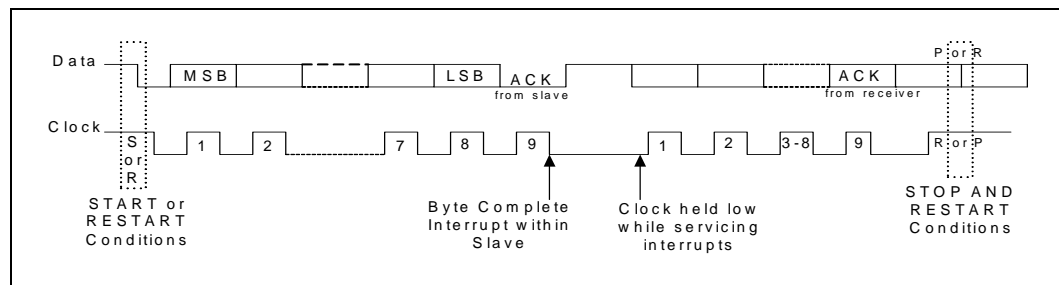

However, according to the I²C specification, standard mode devices are not upward compatible and should not be incorporated in a fast-mode I²C bus system since they cannot follow the higher transfer rate and unpredictable states would occur.

26.2.3 Functional Description

- The I²C master is responsible for generating the clock and controlling the transfer of data.
- The slave is responsible for either transmitting or receiving data to/from the master.
- The acknowledgement of data is sent by the device that is receiving data, which can be either a master or a slave.
- Each slave has a unique address that is determined by the system designer:
 - When a master wants to communicate with a slave, the master transmits a START/RESTART condition that is then followed by the slave's address and a control bit (R/W), to determine if the master wants to transmit data or receive data from the slave.
 - The slave then sends an acknowledge (ACK) pulse after the address.
- If the master (master-transmitter) is writing to the slave (slave-receiver)
 - The receiver gets one byte of data.
 - This transaction continues until the master terminates the transmission with a STOP condition.
- If the master is reading from a slave (master-receiver)
 - The slave transmits (slave-transmitter) a byte of data to the master, and the master then acknowledges the transaction with the ACK pulse.
 - This transaction continues until the master terminates the transmission by not acknowledging (NACK) the transaction after the last byte is received, and then the master issues a STOP condition or addresses another slave after issuing a RESTART condition. This behavior is illustrated in below figure.

Figure 120. Data Transfer on the I²C Bus

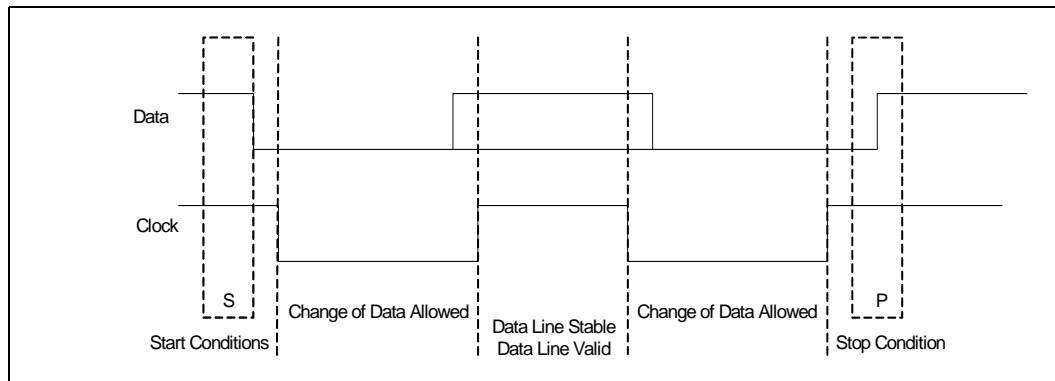

26.2.3.1 START and STOP Conditions

When the bus is idle, both the clock and data signals are pulled high through external pull-up resistors on the bus.

When the master wants to start a transmission on the bus, the master issues a START condition.

- This is defined to be a high-to-low transition of the data signal while the clock is high.
- When the master wants to terminate the transmission, the master issues a STOP condition. This is defined to be a low-to-high transition of the data line while the clock is high. [Figure 121](#) shows the timing of the START and STOP conditions.
- When data is being transmitted on the bus, the data line must be stable when the clock is high.

Figure 121. START and STOP Conditions

The signal transitions for the START/STOP conditions, as depicted above, reflect those observed at the output of the master driving the I²C bus. Care should be taken when observing the data/clock signals at the input of the slave(s), because unequal line delays may result in an incorrect data/clock timing relationship.

26.2.3.2 Addressing Slave Protocol

There are two address formats—seven-bit address format and 10-bit address format.

Seven-bit Address Format

- During the seven-bit address format, the first seven bits (bits 7:1) of the first byte set the slave address and the LSB bit (bit 0) is the R/W bit as shown in [Figure 122](#).
- When bit 0 (R/W) is set to 0, the master writes to the slave. When bit 0 (R/W) is set to 1, the master reads from the slave.

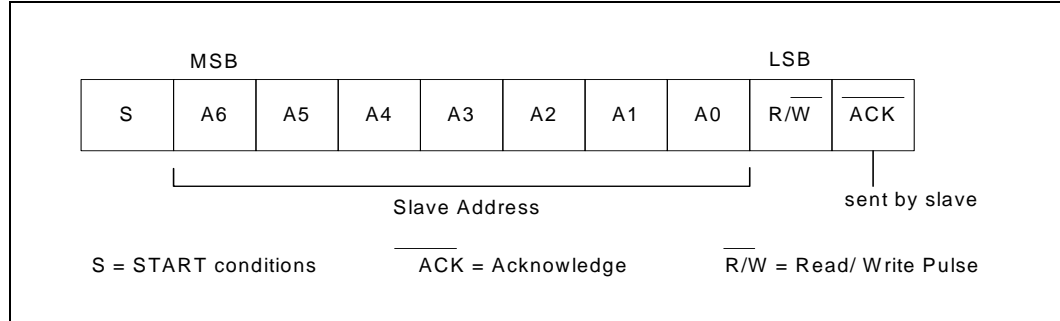

Figure 122. Seven-Bit Address Format

Ten-bit Address Format

- During 10-bit addressing, 2 bytes are transferred to set the 10-bit address. The transfer of the first byte contains the following bit definition.
 - The first five bits (bits 7:3) notify the slaves that this is a 10-bit transfer. The next two bits (bits 2:1) set the slaves address bits 9:8, and the LSB bit (bit 0) is the RW bit.
 - The second byte transferred sets bits 7:0 of the slave address.
 - Figure 123 shows the 10-bit address format, and Table 258 defines the special purpose and reserved first byte addresses.

26.2.3.3 Transmit and Receive Protocol

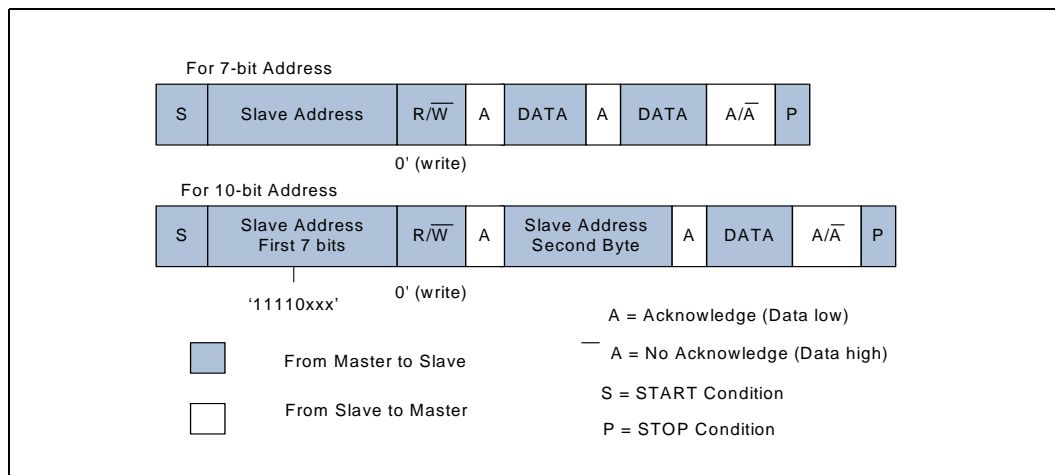

The master can initiate data transmission and reception to/from the bus, acting as either a master-transmitter or master-receiver. A slave responds to requests from the master by either transmitting data or receiving data to/from the bus, acting as either a slave-transmitter or slave-receiver, respectively.

Master-Transmitter and Slave-Receiver

All data is transmitted in byte format, with no limit on the number of bytes transferred per data transfer. After the master sends the address and RW bit or the master transmits a byte of data to the slave, the slave-receiver must respond with the acknowledge signal (ACK). When a slave-receiver does not respond with an ACK pulse, the master aborts the transfer by issuing a STOP condition. The slave must leave the data line high so that the master can abort the transfer.

If the master-transmitter is transmitting data as shown in Figure 124, then the slave-receiver responds to the master-transmitter with an acknowledge pulse after every byte of data is received.

Figure 124. Master Transmitter Protocol

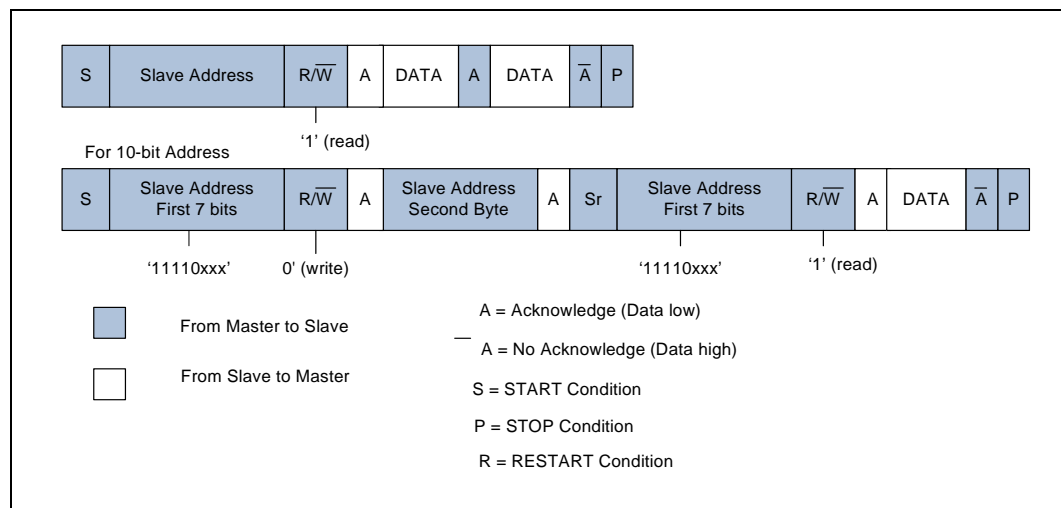

Master-Receiver and Slave-Transmitter

If the master is receiving data as shown in Figure 125, the master responds to the Slave-Transmitter with an acknowledge pulse after a byte of data has been received, except for the last byte. This is the way the Master-Receiver notifies the Slave-Transmitter that this is the last byte. The Slave-Transmitter relinquishes the data line after detecting the No Acknowledge (NACK) so that the master can issue a STOP condition.

When a master does not want to relinquish the bus with a STOP condition, the master can issue a RESTART condition. This is identical to a START condition except it occurs after the ACK pulse. The master can then communicate with the same slave or a different slave.

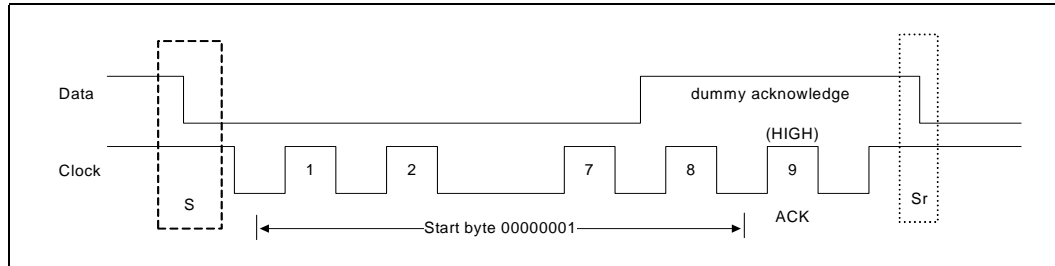

Figure 125. Master Receiver Protocol

26.2.3.4 START BYTE Transfer Protocol

The START BYTE Transfer protocol is set up for systems that do not have an on-board dedicated I²C hardware module. When the I²C controller is a master, it supports the generation of START BYTE transfers at the beginning of every transfer in case a slave device requires it. This protocol consists of 7 '0's being transmitted followed by a 1, as illustrated in Figure 126. This allows the processor that is polling the bus to under-sample the address phase until 0s are detected. Once the microcontroller detects a 0, it switches from the under sampling rate to the correct rate of the master.

Figure 126. START Byte Transfer

The START BYTE procedure is as follows:

1. Master generates a START condition.
2. Master transmits the START byte (0000 0001).
3. Master transmits the ACK clock pulse. (Present only to conform with the byte handling format used on the bus.)
4. No slave sets the ACK signal to 0.
5. Master generates a RESTART (R) condition.

A hardware receiver does not respond to the START BYTE because it is a reserved address and resets after the RESTART condition is generated.

26.3 Use

26.3.1 Master Mode Operation

To use the I²C controller as a master, perform the following steps:

1. Disable the I²C controller by writing 0 (zero) to IC_ENABLE.ENABLE.
2. Write to the IC_CON register to set the maximum speed mode supported for slave operation IC_CON.SPEED and to specify whether the I²C controller starts its transfers in 7/10 bit addressing mode when the device is a slave (IC_CON.IC_10BITADDR_SLAVE).
3. Write to the IC_TAR register the address of the I²C device to be addressed. It also indicates whether a General Call or a START BYTE command is going to be performed by I²C. The desired speed of the I²C controller master-initiated transfers, either 7-bit or 10-bit addressing, is controlled by the IC_TAR.IC_10BITADDR_MASTER bit field.
4. Write to the IC_HS_MADDR register the desired master code for the I²C controller. The master code is programmer-defined.
5. Enable the I²C controller by writing a 1 in IC_ENABLE.
6. Now write the transfer direction and data to be sent to the IC_DATA_CMD register. If the IC_DATA_CMD register is written before the I²C controller is enabled, the

data and commands are lost as the buffers are kept cleared when the I²C controller is not enabled.

The I²C controller supports dynamic updating of the IC_TAR.IC_TAR and IC_TAR.IC_10BITADDR_MASTER. The IC_TAR register can be dynamically written to provided the following conditions are met:

- The I²C controller is not enabled (IC_ENABLE.ENABLE=0)

OR

- The I²C controller is enabled (IC_ENABLE.ENABLE=1); AND the I²C controller is NOT engaged in any Master (tx, rx) operation (IC_STATUS.MST_ACTIVITY=0); AND the I²C controller is enabled to operate in Master mode (IC_CON.MASTER_MODE=1); AND there are NO entries in the TX FIFO (IC_STATUS.TFE=1)

The I²C controller supports switching back and forth between reading and writing dynamically. To transmit data, write the data to be written to the lower byte of the I²C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD). The IC_DATA_CMD.CMD should be written to 0 for I²C write operations. Subsequently, a read command may be issued by writing "don't cares" to IC_DATA_CMD.DAT register bits, and a 1 should be written to the IC_DATA_CMD.CMD bit.

26.3.2 Disabling the I²C Controller

The register IC_ENABLE allows software to unambiguously determine when the hardware has completely shutdown in response to the IC_ENABLE.ENABLE register being cleared from 1 to 0.

Procedure

1. Define a timer interval (t_{i2c_poll}) equal to 10 times the signaling period for the highest I²C transfer speed used in the system and supported by the I²C controller. For example, if the highest I²C transfer mode is 400Kb/s, then this t_{i2c_poll} is 25 μ s.
2. Define a maximum time-out parameter, MAX_T_POLL_COUNT, such that if any repeated polling operation exceeds this maximum value, an error is reported.
3. Execute a blocking thread/process/function that prevents any further I²C master transactions to be started by software, but allows any pending transfers to be completed.
4. The variable POLL_COUNT is initialized to zero (0).
5. Clear IC_ENABLE.ENABLE to zero (0).
6. Read the IC_ENABLE_STATUS.IC_EN bit. Increment POLL_COUNT by one. If POLL_COUNT \geq MAX_T_POLL_COUNT, exit with the relevant error code.
7. If IC_ENABLE_STATUS.IC_EN is 1, then sleep for t_{i2c_poll} and proceed to the previous step. Otherwise, exit with a relevant success code.

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Device ID (DEVICEID) : Device ID identifies the particular AHB device. This is tied to a strap at the top level.
15:0	8086h RO	Vendor ID (VENDORID) : Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

26.6.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 8h

Default: 00000000h

CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

26.6.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + Ch

Default: 00800000h

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	1h RO	Multi Function Device (MULFNDEV): This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. <ul style="list-style-type: none"> 1 = multifunction device 0 = single function device
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

26.6.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	Size Indicator Read Only (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	Type (TYPE) : 00 indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE) : 0. Indicates this BAR is present in the memory space.

26.6.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 14h

Default: 00000000h

31:12	00000h RW	Base Address Register 1 (BASEADDR1) : BAR1 of the LPIO device.
11:4	00h RO	SIZEINDICATOR1 : Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1) : Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1) : 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1) : 0. Indicates this BAR is present in the memory space.

26.6.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

26.6.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 30h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

26.6.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0 : Reserved.
7:0	00h RO	Capabilities Pointer (CAPPTR_POWER) : Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

26.6.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 3Ch

Default: 00000100h

MAX_LAT				MIN_GNT				Reserved0		INTPIN		INTLINE	

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0 : Reserved.
11:8	1h RO	Interrupt Pin (INTPIN) : Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE) : Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

26.6.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + 80h

Bit Range	Default & Access	Field Name (ID): Description
15	0h RW/1C	PME Status (PMESTATUS): <ul style="list-style-type: none"> 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PME Enable (PMEENABLE): A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	No_Soft_Reset (NO_SOFT_RESET): This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	Power State (POWERSTATE): This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

26.6.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:1] + F8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Manufacturer ID (MANID): This register is brought out as straps to the top level.

26.7.2 I2C Target Address Register (IC_TAR)—Offset 4h

Writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND
- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Bit Range	Default & Access	Field Name (ID): Description
31:13	0b RW	Reserved_13_31: Reserved.
12	1h RW	IC_10BITADDR_MASTER: This bit controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master.
11	0h RW	SPECIAL: This bit indicates whether software performs a General Call or START BYTE command. <ul style="list-style-type: none"> • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	GC_OR_START: If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	IC_TAR: This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

Bit Range	Default & Access	Field Name (ID): Description
31:3	0b RW	Reserved_3_31: Reserved.
2:0	1h RW	IC_HS_MAR: This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.7.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

Bit Range	Default & Access	Field Name (ID): Description
31:11	0b RW	Reserved_11_31: Reserved.
10	0h RW	RESTART: This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	STOP: This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	CMD: This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. <ul style="list-style-type: none"> 1 = Read 0 = Write

26.7.9 Fast Speed I2C Clock SCL Low Count Register (IC_FS_SCL_LCNT)—Offset 20h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock low period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL.

4	0h RO	R_TX_EMPTY : This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register.
3	0h RO	R_TX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH, and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
2	0h RO	R_RX_FULL : Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register.
1	0h RO	R_RX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
0	0h RO	R_RX_UNDER : Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register.

26.7.13 I2C Interrupt Mask Register (IC_INTR_MASK)—Offset 30h

These bits mask their corresponding interrupt status bits. This register is active low.

- 0 masks the interrupt
- 1 unmasks the interrupt

26.7.29 I2C Status Register (IC_STATUS)—Offset 70h

This is a read-only register used to indicate the current transfer status and FIFO status. The status register may be read at any time. None of the bits in this register request an interrupt. The following occurs when the I2C is disabled by writing 0 in bit 0 of the IC_ENABLE register:

- Bits 1 and 2 are set to 1
- Bits 3 and 4 are set to 0

When the master or slave state machines goes to idle and ic_en=0:

26.7.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

26.7.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.7.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

26.7.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

26.7.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable (URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

26.8.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:2] + 8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

26.8.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	1h RO	Multi Function Device (MULFNDEV): This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. <ul style="list-style-type: none"> 1 = multifunction device 0 = single function device
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

Bit Range	Default & Access	Field Name (ID): Description
11:4	00h RO	SIZEINDICATOR1 : Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1) : Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1) : 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1) : 0. Indicates this BAR is present in the memory space.

26.8.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register

SUBSYSTEMID				SUBSYSTEMVENDORID				

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID) : This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID) : This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

26.8.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:2] + 30h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

26.8.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:2] + 34h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0: Reserved.
7:0	00h RO	Capabilities Pointer (CAPPTR_POWER): Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

Bit Range	Default & Access	Field Name (ID): Description
3	1h RO	No_Soft_Reset (NO_SOFT_RESET) : This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3 : Reserved.
1:0	0h RW	Power State (POWERSTATE) : This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

26.8.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:2] + F8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Manufacturer ID (MANID) : This register is brought out as straps to the top level.

26.9.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000055h

Bit Range	Default & Access	Field Name (ID): Description
31:10	0b RW	Reserved_10_31: Reserved.
9:0	55h RW	IC_SAR: The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.9.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000001h

Bit Range	Default & Access	Field Name (ID): Description
31:3	0b RW	Reserved_3_31 : Reserved.
2:0	1h RW	IC_HS_MAR : This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.9.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:24, F:2] + 10h

Bit Range	Default & Access	Field Name (ID): Description
31:11	0b RW	Reserved_11_31 : Reserved.
10	0h RW	RESTART : This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	STOP : This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	CMD : This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. <ul style="list-style-type: none"> 1 = Read 0 = Write

Bit Range	Default & Access	Field Name (ID): Description
7:0	0h RW	DAT: This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

26.9.6 Standard Speed I2C Clock SCL High Count Register (IC_SS_SCL_HCNT)—Offset 14h

This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock high-period count for standard speed.

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

26.9.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.9.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

31:24	0h RO	TX_FLUSH_CNT: This field preserves the TXFLR value prior to the last TX_ABRT event. It is enabled when fix_ctrl_1680 = 1. It is cleared whenever I2C is disabled.
23:17	0b RW	Reserved_17_23: Reserved
16	0h RO	ABRT_USER_ABRT: This is a master-mode only bit. Master has detected the user initiated transfer abort (IC_ENABLE[1]). It is enabled only when fix_ctrl_1680 = 1
15	0h RO	ABRT_SLVRD_INTX: 1 = When the processor side responds to a slave mode request for data to be transmitted to a remote master and user writes a 1 in CMD (bit 8) of IC_DATA_CMD register.
14	0h RO	ABRT_SLV_ARBLOST: 1 = Slave lost the bus while transmitting data to a remote master. IC_TX_ABRT_SOURCE[12] is set at the same time.
13	0h RO	ABRT_SLVFLUSH_TXFIFO: 1 = Slave has received a read command and some data exists in the TX FIFO so the slave issues a TX_ABRT interrupt to flush old data in TX FIFO.
12	0h RO	ARB_LOST: 1 = Master has lost arbitration, or if IC_TX_ABRT_SOURCE[14] is also set, then the slave transmitter has lost arbitration.
11	0h RO	ABRT_MASTER_DIS: 1 = User tries to initiate a Master operation with the Master mode disabled.
10	0h RO	ABRT_10B_RD_NORSTRT: 1 = The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the master sends a read command in 10-bit addressing mode.
9	0h RO	ABRT_SBYTE_NORSTRT: 1 = The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the user is trying to send a START Byte.
8	0h RO	ABRT_HS_NORSTRT: 1 = The restart is disabled (IC_RESTART_EN bit (IC_CON[5]) = 0) and the user is trying to use the master to transfer data in High Speed mode.
7	0h RO	ABRT_SBYTE_ACKDET: 1 = Master has sent a START Byte and the START Byte was acknowledged (wrong behavior).

Bit Range	Default & Access	Field Name (ID): Description
6	0h RO	ABRT_HS_ACKDET : 1 = Master is in High Speed mode and the High Speed Master code was acknowledged (wrong behavior).
5	0h RO	ABRT_GCALL_READ : 1 = DW_apb_i2c in master mode sent a General Call but the user programmed the byte following the General Call to be a read from the bus (IC_DATA_CMD[9] is set to 1).
4	0h RO	ABRT_GCALL_NOACK : 1 = DW_apb_i2c in master mode sent a General Call and no slave on the bus acknowledged the General Call.
3	0h RO	ABRT_TXDATA_NOACK : 1 = This is a master-mode only bit. Master has received an acknowledgement for the address, but when it sent data byte(s) following the address, it did not receive an acknowledge from the remote slave(s).
2	0h RO	ABRT_10ADDR2_NOACK : 1 = Master is in 10-bit address mode and the second address byte of the 10-bit address was not acknowledged by any slave.
1	0h RO	ABRT_10ADDR1_NOACK : 1 = Master is in 10-bit address mode and the first 10-bit address byte was not acknowledged by any slave.
0	0h RO	ABRT_7B_ADDR_NOACK : 1 = Master is in 7-bit addressing mode and the address sent was not acknowledged by any slave.

26.9.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

26.9.37 I2C Receive Data Level Register (IC_DMA_RDLR)—Offset 90h

This register is only valid when DW_apb_i2c is configured with a set of DMA interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist, writing to its address has no effect, and reading from its address returns zero.

The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE = 1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

26.9.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

26.9.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

26.9.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

26.9.41 IC_FS_SPKLEN—Offset A0h

This register is used to store the duration, measured in ic_clk cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in SS or FS modes. The relevant I2C requirement is tSP (Table 4) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1.

Bit Range	Default & Access	Field Name (ID): Description
31	0h RO	Reserved0: Reserved.
30	0h RW/1C	SSE: Reserved.
29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	Received Target Abort (RTA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	STA: Reserved.
26:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

26.10.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:3] + 8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

26.10.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	1h RO	Multi Function Device (MULFNDEV): This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. <ul style="list-style-type: none"> 1 = multifunction device 0 = single function device
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

26.10.5 Base Address Register (BAR)—Offset 10h

Access Method

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	Size Indicator Read Only (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	Type (TYPE) : 00 indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE) : 0. Indicates this BAR is present in the memory space.

26.10.6 Base Address Register 1 (BAR1)—Offset 14h

31:12	00000h RW	Base Address Register 1 (BASEADDR1) : BAR1 of the LPIO device.
11:4	00h RO	SIZEINDICATOR1 : Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1) : Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1) : 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1) : 0. Indicates this BAR is present in the memory space.

26.10.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:3] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

26.10.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:3] + 30h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

26.10.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:3] + 34h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Reserved0: Reserved.
7:0	00h RO	Capabilities Pointer (CAPPTR_POWER): Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

26.10.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0 : Reserved.
11:8	1h RO	Interrupt Pin (INTPIN) : Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE) : Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

26.10.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Bit Range	Default & Access	Field Name (ID): Description
3	1h RO	No_Soft_Reset (NO_SOFT_RESET) : This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3 : Reserved.
1:0	0h RW	Power State (POWERSTATE) : This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

26.10.13 Manufacturer ID (MANID)—Offset F8h

Bit Range	Default & Access	Field Name (ID): Description
31:7	0b RW	Reserved_7_31: Reserved.
6	1h RW	IC_SLAVE_DISABLE: This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	IC_RESTART_EN: Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: <ul style="list-style-type: none"> • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only): Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	IC_10BITADDR_SLAVE: When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	SPEED: These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	MASTER MODE (MASTER_MODE): This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

26.11.2 I2C Target Address Register (IC_TAR)—Offset 4h

Writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND
- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

2:0	1h RW	IC_HS_MAR: This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.11.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

26.11.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns. This register goes away and becomes read-only if IC_MAX_SPEED_MODE != high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

26.11.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

26.11.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.11.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

26.11.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

26.11.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

0	1h RW	ACK General Call (ACK_GEN_CALL): When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

26.11.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

This register sets the duration, measured in <i>ic_clk</i> cycles, of the longest spike in the SCL or SDA lines that are filtered out by the spike suppression logic; for more information, refer to Spike Suppression on page 52. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 2 being set.

26.11.42 IC_HS_SPKLEN—Offset A4h

This register is used to store the duration, measured in *ic_clk* cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in HS mode. The relevant I2C requirement is *tSP* (Table 6) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1

Reserved_7_31							IC_SLAVE_DISABLE	IC_RESTART_EN	IC_10BITADDR_MASTER_rd_only	IC_10BITADDR_SLAVE	SPEED	MASTER_MODE

Bit Range	Default & Access	Field Name (ID): Description
31:7	0b RW	Reserved_7_31: Reserved.
6	1h RW	IC_SLAVE_DISABLE: This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	IC_RESTART_EN: Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: <ul style="list-style-type: none"> • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only): Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	IC_10BITADDR_SLAVE: When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	SPEED: These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	MASTER MODE (MASTER_MODE): This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

26.13.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

Access Method

Type: Memory Mapped I/O Register

26.13.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

31:3	0b RW	Reserved_3_31: Reserved.
2:0	1h RW	IC_HS_MAR: This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. 9	0h RO	R_STOP_DET : Indicates whether a STOP condition has occurred on the I2C interface, regardless of whether DW_apb_i2c is operating in slave or master mode.
8	0h RO	R_ACTIVITY : This bit captures DW_apb_i2c activity and stays set until it is cleared. There are four ways to clear it: Disabling the DW_apb_i2c, Reading the IC_CLR_ACTIVITY register, Reading the IC_CLR_INTR register, System reset
7	0h RO	R_RX_DONE : When the DW_apb_i2c is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.
6	0h RO	R_TX_ABRT : This bit indicates whether DW_apb_i2c, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO.
5	0h RO	R_RD_REQ : This bit is set to 1 when DW_apb_i2c is acting as a slave and another I2C master is attempting to read data from DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO	R_TX_EMPTY : This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register.
3	0h RO	R_TX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH, and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
2	0h RO	R_RX_FULL : Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register.
1	0h RO	R_RX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
0	0h RO	R_RX_UNDER : Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register.

26.13.31 I2C Receive FIFO Level Register (IC_RXFLR)—Offset 78h

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

26.13.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of `ic_clk` period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when `IC_ENABLE=0`. The programmed SDA hold time cannot exceed at any time the duration of the low part of `scl`. Therefore the programmed value cannot be larger than `N_SCL_LOW-2`, where `N_SCL_LOW` is the duration of the low part of the `scl` period measured in `ic_clk` cycles.

26.13.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the `TX_ABRT` bit. Except for Bit 9, this register is cleared whenever the `IC_CLR_TX_ABRT` register or the `IC_CLR_INTR` register is read. To clear Bit 9, the source of the `ABRT_SBYTE_NORSTRT` must be fixed first; `RESTART` must be enabled (`IC_CON[5]=1`), the `SPECIAL` bit must be cleared (`IC_TAR[11]`), or the `GC_OR_START` bit must be cleared (`IC_TAR[10]`). Once the source of the `ABRT_SBYTE_NORSTRT` is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

26.13.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

26.13.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

26.13.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID) : This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID) : This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

26.15.2 I2C Target Address Register (IC_TAR)—Offset 4h

Writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND
- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

31:13	0b RW	Reserved_13_31: Reserved.
12	1h RW	IC_10BITADDR_MASTER: This bit controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master.
11	0h RW	SPECIAL: This bit indicates whether software performs a General Call or START BYTE command. <ul style="list-style-type: none"> • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	GC_OR_START: If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	IC_TAR: This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

Bit Range	Default & Access	Field Name (ID): Description
31:3	0b RW	Reserved_3_31: Reserved.
2:0	1h RW	IC_HS_MAR: This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.15.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

31:11	0b RW	Reserved_11_31: Reserved.
10	0h RW	RESTART: This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	STOP: This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	CMD: This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. <ul style="list-style-type: none"> 1 = Read 0 = Write

26.15.9 Fast Speed I2C Clock SCL Low Count Register (IC_FS_SCL_LCNT)—Offset 20h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock low period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL.

4	0h RO	R_TX_EMPTY : This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register.
3	0h RO	R_TX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH, and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
2	0h RO	R_RX_FULL : Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register.
1	0h RO	R_RX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
0	0h RO	R_RX_UNDER : Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register.

26.15.13 I2C Interrupt Mask Register (IC_INTR_MASK)—Offset 30h

These bits mask their corresponding interrupt status bits. This register is active low.

- 0 masks the interrupt
- 1 unmasks the interrupt

26.15.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

26.15.31 I2C Receive FIFO Level Register (IC_RXFLR)—Offset 78h

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

26.15.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.15.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

26.15.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

26.15.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

26.15.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Field Name (ID): Description

26.17.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000055h

Bit Range	Default & Access	Field Name (ID): Description
31:10	0b RW	Reserved_10_31: Reserved.
9:0	55h RW	IC_SAR: The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.17.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000001h

Bit Range	Default & Access	Field Name (ID): Description
31:3	0b RW	Reserved_3_31 : Reserved.
2:0	1h RW	IC_HS_MAR : This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

26.17.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

Access Method

Type: Memory Mapped I/O Register

Bit Range	Default & Access	Field Name (ID): Description
31:11	0b RW	Reserved_11_31 : Reserved.
10	0h RW	RESTART : This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	STOP : This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	CMD : This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. <ul style="list-style-type: none"> 1 = Read 0 = Write

7:0	0h RW	DAT: This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

26.17.6 Standard Speed I2C Clock SCL High Count Register (IC_SS_SCL_HCNT)—Offset 14h

This register must be set before any I2C bus transaction can take place to ensure proper I/O timing. This register sets the SCL clock high-period count for standard speed.

26.17.12 I2C Interrupt Status Register (IC_INTR_STAT)—Offset 2Ch

Each bit in this register has a corresponding mask bit in the IC_INTR_MASK register. These bits are cleared by reading the matching interrupt clear register. The unmasked raw versions of these bits are available in the IC_RAW_INTR_STAT register.

Access Method

Type: Memory Mapped I/O Register

Bit Range	Default & Access	Field Name (ID): Description
31:12	0b RW	Reserved_12_31 : Reserved.
11	0h RO	R_GEN_CALL : Set only when a General Call address is received and acknowledged. It stays set until it is cleared either by disabling DW_apb_i2c or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register.
10	0h RO	R_START_DET : Indicates whether a START or RESTART condition has occurred on the I2C interface, regardless of whether DW_apb_i2c is operating in slave or master mode.
9	0h RO	R_STOP_DET : Indicates whether a STOP condition has occurred on the I2C interface, regardless of whether DW_apb_i2c is operating in slave or master mode.
8	0h RO	R_ACTIVITY : This bit captures DW_apb_i2c activity and stays set until it is cleared. There are four ways to clear it: Disabling the DW_apb_i2c, Reading the IC_CLR_ACTIVITY register, Reading the IC_CLR_INTR register, System reset
7	0h RO	R_RX_DONE : When the DW_apb_i2c is acting as a slave-transmitter, this bit is set to 1 if the master does not acknowledge a transmitted byte. This occurs on the last byte of the transmission, indicating that the transmission is done.
6	0h RO	R_TX_ABRT : This bit indicates whether DW_apb_i2c, as an I2C transmitter, is unable to complete the intended actions on the contents of the transmit FIFO.
5	0h RO	R_RD_REQ : This bit is set to 1 when DW_apb_i2c is acting as a slave and another I2C master is attempting to read data from DW_apb_i2c.

Bit Range	Default & Access	Field Name (ID): Description
4	0h RO	R_TX_EMPTY : This bit is set to 1 when the transmit buffer is at or below the threshold value set in the IC_TX_TL register.
3	0h RO	R_TX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH, and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
2	0h RO	R_RX_FULL : Set when the receive buffer reaches or goes above the RX_TL threshold in the IC_RX_TL register.
1	0h RO	R_RX_OVER : Set during transmit if the transmit buffer is filled to IC_TX_BUFFER_DEPTH and the processor attempts to issue another I2C command by writing to the IC_DATA_CMD register.
0	0h RO	R_RX_UNDER : Set if the processor attempts to read the receive buffer when it is empty by reading from the IC_DATA_CMD register.

26.17.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.17.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

26.17.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. 29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	Received Target Abort (RTA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	STA: Reserved.
26:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description

2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

26.18.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:7] + 8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	Size Indicator Read Only (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	Type (TYPE) : 00 indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE) : 0. Indicates this BAR is present in the memory space.

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:24, F:7] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

26.19.2 I2C Target Address Register (IC_TAR)—Offset 4h

Writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND
- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

26.19.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns. This register goes away and becomes read-only if IC_MAX_SPEED_MODE != high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

26.19.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

26.19.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0. The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

26.19.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same

manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE = 1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

26.19.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2. **NOTE:** The length of setup time is calculated using $[(IC_SDA_SETUP - 1) * (ic_clk_period)]$, so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

26.19.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

The register controls whether DW_apb_i2c responds with an ACK or NACK when it receives an I2C General Call address.

Access Method

0	1h RW	ACK General Call (ACK_GEN_CALL): When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

26.19.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect. The minimum valid value is 1; hardware prevents values less than this being written, and if attempted results in 2 being set.

26.19.42 IC_HS_SPKLEN—Offset A4h

This register is used to store the duration, measured in *ic_clk* cycles, of the longest spike that is filtered out by the spike suppression logic when the component is operating in HS mode. The relevant I2C requirement is *tSP* (Table 6) as detailed in the I2C Bus Specification. This register must be programmed with a minimum value of 1

27 SIO – High Speed UART

The SoC implements two instances of high speed UART controller that support baud rates between 300 and 3686400. Hardware flow control is also supported.

27.1 Signal Descriptions

Please see [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

27.2 Features

27.2.1 UART Function

The UART transmits and receives data in bit frames as shown in [Figure 128](#).

- Each data frame is between 7 and 12 bits long, depending on the size of data programmed and if parity and stop bits are enabled.
- The frame begins with a start bit that is represented by a high-to-low transition.
- Next, 5 to 8 bits of data are transmitted, beginning with the least significant bit. An optional parity bit follows, which is set if even parity is enabled and an odd number of ones exist within the data byte; or, if odd parity is enabled and the data byte contains an even number of ones.
- The data frame ends with one, one-and-one-half, or two stop bits (as programmed by users), which is represented by one or two successive bit periods of a logic one.

Figure 128. UART Data Transfer Flow

Each UART has a Transmit FIFO and a Receive FIFO and each holds 64 characters of data. There are two separate methods for moving data into/out of the FIFOs—Interruptions and Polling.

27.2.2 Clock and Reset

The BAUD rate generates from serial clock (**Sclock**) frequency which is based on a fixed base/system clock (**Fbase**) of 100 MHz processed through an M/N divider. M/N divider settings are found in the HSUART's PRV_CLOCK_PARAMS register. **Sclock** frequency = (Fbase*M)/N. Some useful Sclock frequencies and related M/N values are shown below:

Table 275. Sclock Frequencies from M/N Settings

M Value	N Value	Sclock
228 (0x120)	15625 (0x3D09)	1.84320 MHz
1024 (0x400)	3125 (0xC35)	32.7680 MHz
9216 (0x2400)	15625 (0x3D09)	58.9824 MHz

27.2.3 Baud Rate Generator

The baud rates for the UARTs are generated with from the serial clock frequency (Sclock) by programming the DLH and DLL registers as a divisor. The hexadecimal value of the **divisor** is (IER_DLH[7:0]<8) | RBR_THR_DLL[7:0].

Fbase is the system clock frequency in Hz (100,000,000 in decimal when the system clock frequency is 100 MHz.).

The output baud rate is as follows:

$$\text{— baud rate} = (\text{Sclock}) / (16 * \text{divisor})$$

Table 276. Baud Rates Achievable with Different DLAB Settings

DLH,DLL Divisor	DLH,DLL Divisor Hexadecimal	Baud Rate

27.3 Use

Each UART has a transmit FIFO and a receive FIFO, each FIFO holding 64 characters of data. Three separate methods move data into and out of the FIFOs: interrupts, DMA, and polled.

27.3.1 DMA Mode Operation

27.3.1.1 Receiver DMA

The data transfer from the HSUART to host memory is controlled by the DMA write channel. To configure the channel in write mode, channel direction in the channel control register needs to be programmed to "1". The software need to program the descriptor start address register, descriptor transfer size register, and descriptor control register before starting the channel using the channel active bit in the channel control register.

27.3.1.2 Transmit DMA

The data transfer from host memory to HSUART is controlled by DMA read channel. To configure the channel in read mode, channel direction in the channel control register needs to be programmed to "0". The software need to program the descriptor start address register, descriptor transfer size register, and descriptor control register before starting the channel using the channel active bit in the channel control register.

27.3.1.3 Removing Trailing Bytes in DMA Mode

When the number of entries in the Receive FIFO is less than its trigger level, and no additional data is received, the remaining bytes are called Trailing bytes. These are DMAed out by the DMA as it has visibility into the FIFO Occupancy register.

27.3.2 FIFO Polled-Mode Operation

With the FIFOs enabled (IIR_FCR.IID0_FIFOE bit set to 1), clearing IER_DLH[7] and IER_DLH[4:0] puts the serial port in the FIFO Polled Operation mode. Because the receiver and the transmitter are controlled separately, either one or both can be in Polled Operation mode. In this mode, software checks Receiver and Transmitter status using the Line Status Register (LSR). The processor polls the following bits for Receive and Transmit Data Service.

27.3.2.1 Receive Data Service

The processor checks data ready (LSR.DR) bit which is set when 1 or more bytes remains in the Receive FIFO or Receive Buffer Register (RBR_THR_DLL).

27.3.2.2 Transmit Data Service

The processor checks transmit data request LSR.THRE bit, which is set when the transmitter needs data.

The processor can also check transmitter empty LSR.TEMT, which is set when the Transmit FIFO or Holding register is empty.

27.3.2.3 Autoflow Control

Autoflow Control uses Clear-to-Send (nCTS) and Request-to-Send (nRTS) signals to automatically control the flow of data between the UART and external modem. When autoflow is enabled, the remote device is not allowed to send data unless the UART asserts nRTS low. If the UART de-asserts nRTS while the remote device is sending data, the remote device is allowed to send one additional byte after nRTS is deasserted. An overflow could occur if the remote device violates this rule. Likewise, the UART is not allowed to transmit data unless the remote device asserts nCTS low. This feature increases system efficiency and eliminates the possibility of a Receive FIFO Overflow error due to long interrupt latency.

Autoflow mode can be used in two ways: Full autoflow, automating both nCTS and nRTS, and half autoflow, automating only nCTS. Full Autoflow is enabled by writing a 1 to bits 1 and 5 of the Modem Control Register (MCR). Auto-nCTS-Only mode is enabled by writing a 1 to bit 5 and a 0 to bit 1 of the MCR register.

27.3.2.4 RTS (UART Output)

When in full autoflow mode, nRTS is asserted when the UART FIFO is ready to receive data from the remote transmitter. This occurs when the amount of data in the Receive FIFO is below the programmable threshold value. When the amount of data in the Receive FIFO reaches the programmable threshold, nRTS is de-asserted. It will be asserted once again when enough bytes are removed from the FIFO to lower the data level below the threshold.

27.3.2.5 CTS (UART Input)

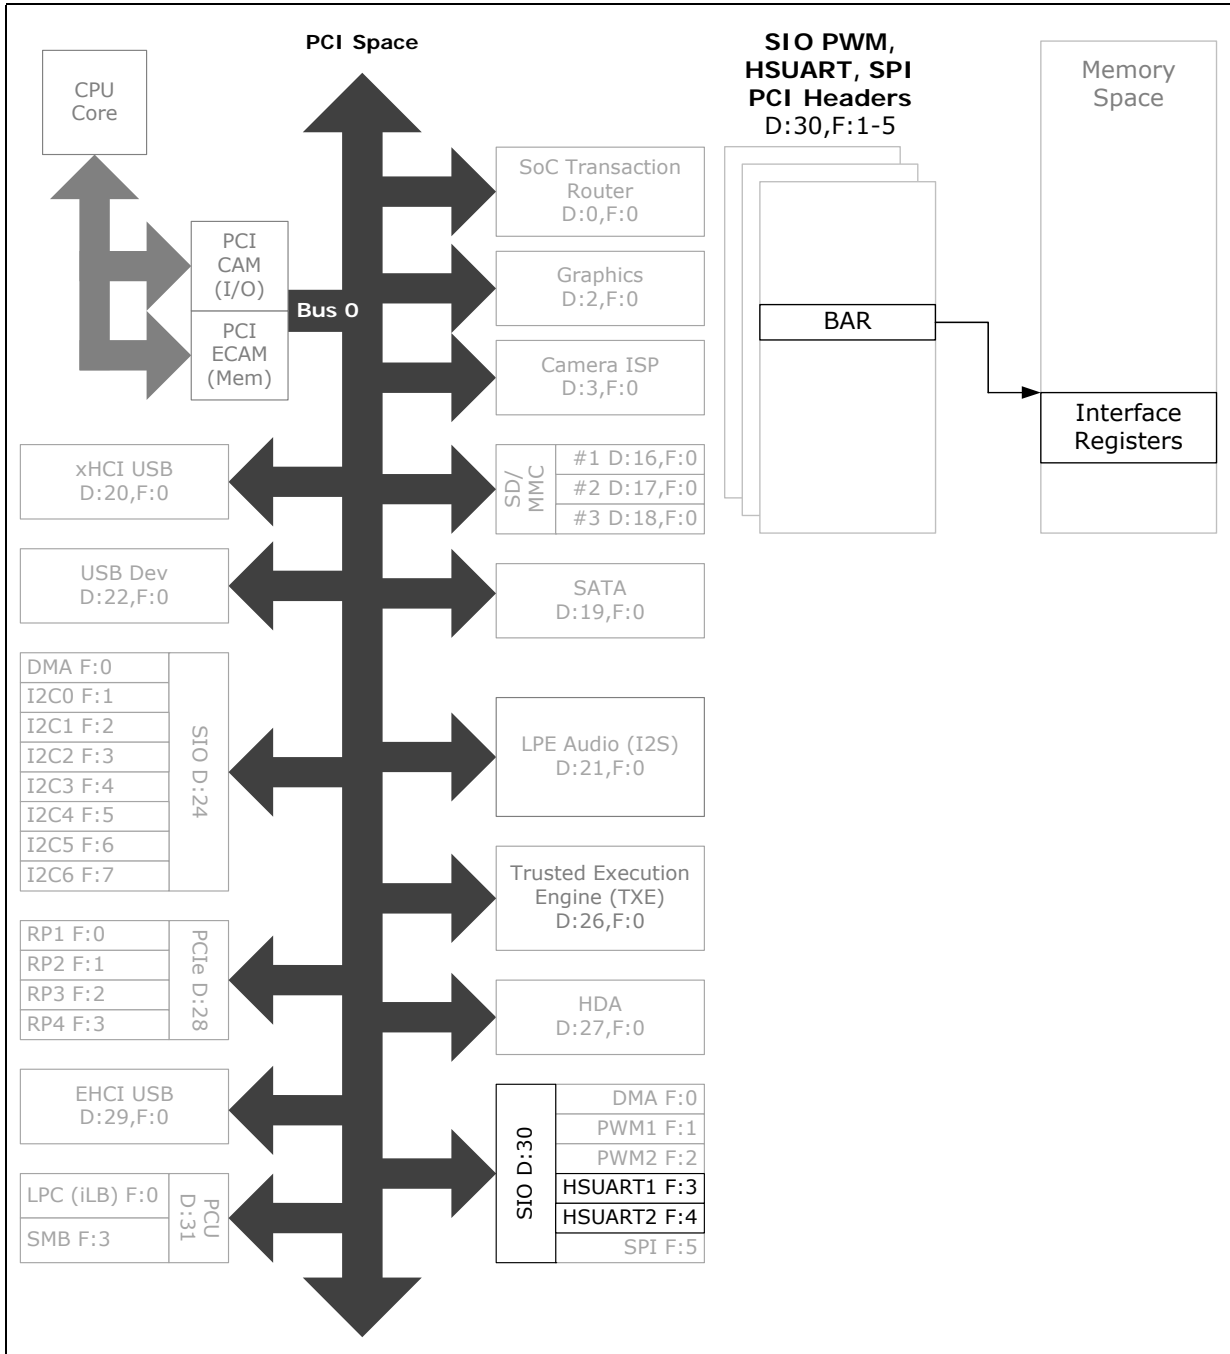

When in Full or Half-Autoflow mode, nCTS is asserted by the remote receiver when the receiver is ready to receive data from the UART. The UART checks nCTS before sending the next byte of data and will not transmit the byte until nCTS is low. If nCTS goes high while the transfer of a byte is in progress, the transmitter will complete this byte.

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RO	Device ID (DEVICEID): Device ID identifies the particular AHB device. This is tied to a strap at the top level.
15:0	8086h RO	Vendor ID (VENDORID): Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

27.5.2 Status and Command (STATUSCOMMAND)—Offset 4h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 4h

Default: 00100000h

Reserved0	SSE	RMA	RTA	STA	Reserved1	CAPLIST	INTR_STATUS	Reserved2	Reserved3	INTR_DISABLE	Reserved4	SERR_ENABLE	Reserved5	BME	MSE	Reserved6

Bit Range	Default & Access	Field Name (ID): Description
31	0h RO	Reserved0: Reserved.
30	0h RW/1C	SSE: Reserved.
29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	Received Target Abort (RTA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	STA: Reserved.
26:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.

Bit Range	Default & Access	Field Name (ID): Description
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	Reserved6: Reserved.

27.5.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 8h

CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

27.5.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + Ch

Default: 00800000h

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Reserved0: Reserved.
23	1h RO	Multi Function Device (MULFNDEV): This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. <ul style="list-style-type: none"> • 1 = multifunction device • 0 = single function device
22:16	00h RO	Header Type (HEADERTYPE): Implements Type 0 Configuration header.
15:8	00h RO	Latency Timer (LATTIMER): Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	Cache Line Size (CACHELINE_SIZE): Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

27.5.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address (BASEADDR): Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	Size Indicator Read Only (SIZEINDICATOR): Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE): Indicates that this BAR is not prefetchable.

Bit Range	Default & Access	Field Name (ID): Description
2:1	0h RO	Type (TYPE) : 00 indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE) : 0. Indicates this BAR is present in the memory space.

27.5.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 14h

Bit Range	Default & Access	Field Name (ID): Description
31:12	00000h RW	Base Address Register 1 (BASEADDR1) : BAR1 of the LPIO device.
11:4	00h RO	SIZEINDICATOR1 : Always will be zero as minimum size is 4K.
3	0h RO	Prefetchable (PREFETCHABLE1) : Indicates that this BAR is not.
2:1	0h RO	Type (TYPE1) : 00 Indicates BAR lies in 32 bit address range.
0	0h RO	Memory Space Indicator (MESSAGE_SPACE1) : 0. Indicates this BAR is present in the memory space.

27.5.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 2Ch

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

27.5.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 30h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	EXPANSION_ROM_BASE: Reserved.

27.5.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Bit Range	Default & Access	Field Name (ID): Description
31:24	00h RO	Max_Lat (MAX_LAT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	Min_Gnt (MIN_GNT) : Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	Reserved0 : Reserved.
11:8	1h RO	Interrupt Pin (INTPIN) : Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	Interrupt Line (INTLINE) : Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

27.5.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + 80h

Bit Range	Default & Access	Field Name (ID): Description
15	0h RW/1C	PME Status (PMESTATUS): <ul style="list-style-type: none"> 0 = Software clears the bit by writing a 1 to it. 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).
14:9	00h RO	Reserved1: Reserved.
8	0h RW	PME Enable (PMEENABLE): A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	Reserved2: Reserved.
3	1h RO	No_Soft_Reset (NO_SOFT_RESET): This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	Reserved3: Reserved.
1:0	0h RW	Power State (POWERSTATE): This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: <ul style="list-style-type: none"> 00 = D0 state 11 = D3HOT state Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

27.5.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

Offset: [B:0, D:30, F:3] + F8h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:0	00000000h RO	Manufacturer ID (MANID): This register is brought out as straps to the top level.

27.6.1 Receive Buffer Register/Transmit Holding Register/Divisor Latch (Low). (RBR_THR_DLL)—Offset 0h

Register is used for different purposes depending on the mode. See description details

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

Offset: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)

BAR Reference: [B:0, D:30, F:3] + 10h

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:8	0b RO	RSVDO: Reserved
7:0	0h RW	<p>rbr_thr_dll: RBR[7:0] (Receive Buffer Register) (Read Only): Data byte received on the serial input port (sin) in UART mode. The data in this register is valid only if the Data Ready (DR) bit in the Line Status Register (LCR) is set. If FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an over-run error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO is preserved, but any incoming data are lost and an over-run error occurs.</p> <p>THR[7:0] (Transmit Holding Register) (Write Only): Data to be transmitted on the serial output port (sout) in UART mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] = 0) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] = 1) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configuration. Any attempt to write data when the FIFO is full results in the write data being lost.</p> <p>DLL[7:0] (Divisor Latch Low) (Read-Write): Lower 8 bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. this register may be accessed only when the DLAB bit (LCR[7]) is set. The output baud rate is equal to the serial frequency divided by sixteen times the value of the baud rate divisor, as follows: $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$. Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLL is set, at least 8 clock cycles of the slowest HSUART clock should be allowed to pass before transmitting or receiving data.</p>

27.6.2 Divisor Latch (High)/ Interrupt Enable Register. (IER_DLH)—Offset 4h

Register bits [7:0] is used for different purposes depending on the mode. DLH (Divisor Latch High) Upper 8-bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may be accessed only when the DLAB bit (LCR[7]) is set. The output baud rate is equal to the serial clock frequency divided by sixteen times the value of the baud rate divisor, as follows: $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$. Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLH is set, at least 8 clock cycles of the slowest HSUART clock should be allowed to pass before transmitting or receiving data.

7:6	0h RW	FIFOSE_RCVR (RCVR): FIFOSE (FIFOs Enabled) This is used to indicate whether the FIFOs are enabled or disabled. 00 = disabled 11 = enabled RCVR Trigger. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. It also determines when the dma_rx_req_n signal is asserted in certain modes of operation. The following trigger levels are supported: <ul style="list-style-type: none"> 00 = 1 character in the FIFO 01 = FIFO full 10 = FIFO full 11 = FIFO 2 less than full
5:4	0h RW	Res_TET (TET): TX Empty Trigger. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. It also determines when the dma_tx_req_n signal is asserted when in certain modes of operation. The following trigger levels are supported: <ul style="list-style-type: none"> 00 = FIFO empty 01 = 2 characters in the FIFO 10 = FIFO full 11 = FIFO full
3	0h RW	IID3_DMAM (DMAM): DMA Mode. Reserved
2	0h RW	IID2_XFIFOR (XFIFOR): XMIT FIFO Reset. This resets the control portion of the transmit FIFO and treats the FIFO as empty. Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
1	0h RW	IID1_RFIFOR (RFIFOR): RCVR FIFO Reset. This resets the control portion of the receive FIFO and treats the FIFO as empty. Note that this bit is 'self-clearing'. It is not necessary to clear this bit.
0	1h RW	IID0_FIFO Enable (FIFOE): This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset

Bit Range	Default & Access	Field Name (ID): Description
31:6	0b RO	RSVDO: Reserved
5	0h RW	Auto Flow Control Enable (AFCE): When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, <ul style="list-style-type: none"> 0 = Auto Flow Control Mode disabled 1 = Auto Flow Control Mode enabled Reset Value: 0x0
4	0h RW	LoopBack Bit (LoopBack): This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. Reset Value: 0x0
3	0h RW	Output2 (OUT2): This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: <ul style="list-style-type: none"> 0 = out2_n de-asserted (logic 1) 1 = out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
2	0h RW	Output1 (OUT1): This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: <ul style="list-style-type: none"> 0 = out1_n de-asserted (logic 1) 1 = out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
1	0h RW	Request to Send (RTS): This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. <p>Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0</p>
0	0h RW	Data Terminal Ready (DTR): This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: <ul style="list-style-type: none"> 0 = dtr_n de-asserted (logic 1) 1 = dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Bit Range	Default & Access	Field Name (ID): Description
31:8	0b RO	RSVDO: Reserved
7	0h RW	<p>Receiver FIFO Error Bit (RFE): This bit is only relevant when FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO.</p> <ul style="list-style-type: none"> 0 = no error in RX FIFO 1 = error in RX FIFO <p>This bit is cleared when the LSR is read, the character with the error is at the top of the receiver FIFO, and there are no subsequent errors in the FIFO. Reset Value: 0x0</p>
6	1h RW	<p>Transmitter Empty Bit (TEMT): If FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1</p>
5	1h RW	<p>Transmit Holding Register Empty Bit (THRE): If THRE mode is disabled (IER[7] set to zero), this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE mode is enabled and and FIFOs enabled (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. Reset Value: 0x1</p>
4	0h RW	<p>Break Interrupt Bit (BI): This is used to indicate the detection of a break sequence on the serial input data.</p> <p>If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits.</p> <p>In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.</p>
3	0h RW	<p>Framing Error Bit (FE): This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]).</p> <ul style="list-style-type: none"> 0 = no framing error 1 = framing error <p>Reading the LSR clears the FE bit. Reset Value: 0x0</p>
2	0h RW	<p>Parity Error Bit (PE): This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]).</p> <ul style="list-style-type: none"> 0 = no parity error 1 = parity error <p>Reading the LSR clears the PE bit. Reset Value: 0x0</p>

Bit Range	Default & Access	Field Name (ID): Description
1	0h RW	<p>Overrun Error Bit (OE): This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost.</p> <ul style="list-style-type: none"> 0 = no overrun error 1 = overrun error <p>Reading the LSR clears the OE bit. Reset Value: 0x0</p>
0	0h RW	<p>Data Ready Bit (DR): This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO.</p> <ul style="list-style-type: none"> 0 = no data ready 1 = data ready <p>This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. 31:8	0b RO	RSVDO : Reserved
7:0	0h RW	srbr_sthr0 : This is a shadow register for the RBR and has been allocated sixteen 32-bit locations to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO are preserved, but any incoming data are lost. In Auto Flow Control active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Field Name (ID): Description
31:8	0b RO	RSVDO: Reserved
7:0	0h RW	<p>rbr_thr_dll: RBR[7:0] (Receive Buffer Register) (Read Only): Data byte received on the serial input port (sin) in UART mode. The data in this register is valid only if the Data Ready (DR) bit in the Line Status Register (LCR) is set. If FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an over-run error. If FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. If the receive FIFO is full and this register is not read before the next data character arrives, then the data already in the FIFO is preserved, but any incoming data are lost and an over-run error occurs.</p> <p>THR[7:0] (Transmit Holding Register) (Write Only): Data to be transmitted on the serial output port (sout) in UART mode. Data should only be written to the THR when the THR Empty (THRE) bit (LSR[5]) is set. If in non-FIFO mode or FIFOs are disabled (FCR[0] = 0) and THRE is set, writing a single character to the THR clears the THRE. Any additional writes to the THR before the THRE is set again causes the THR data to be overwritten. If in FIFO mode and FIFOs are enabled (FCR[0] = 1) and THRE is set, x number of characters of data may be written to the THR before the FIFO is full. The number x (default=16) is determined by the value of FIFO Depth that you set during configuration. Any attempt to write data when the FIFO is full results in the write data being lost.</p> <p>DLL[7:0] (Divisor Latch Low) (Read-Write): Lower 8 bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. this register may be accessed only when the DLAB bit (LCR[7]) is set. The output baud rate is equal to the serial frequency divided by sixteen times the value of the baud rate divisor, as follows: $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$. Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLL is set, at least 8 clock cycles of the slowest HSUART clock should be allowed to pass before transmitting or receiving data.</p>

27.8.2 Divisor Latch (High)/ Interrupt Enable Register. (IER_DLH)—Offset 4h

Register bits [7:0] is used for different purposes depending on the mode. DLH (Divisor Latch High) Upper 8-bits of a 16-bit, read/write, Divisor Latch register that contains the baud rate divisor for the UART. This register may be accessed only when the DLAB bit (LCR[7]) is set. The output baud rate is equal to the serial clock frequency divided by sixteen times the value of the baud rate divisor, as follows: $\text{baud rate} = (\text{serial clock freq}) / (16 * \text{divisor})$. Note that with the Divisor Latch Registers (DLL and DLH) set to zero, the baud clock is disabled and no serial communications occur. Also, once the DLH is set, at least 8 clock cycles of the slowest HSUART clock should be allowed to pass before transmitting or receiving data.

4	0h RW	LoopBack Bit (LoopBack): This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. Reset Value: 0x0

Reset Value: 0x0
1	0h RW	Request to Send (RTS): This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0
0	0h RW	Data Terminal Ready (DTR): This is used to directly control the Data Terminal Ready (dtr_n) output. Bit Range	Default & Access	Field Name (ID): Description
31:8	0b RO	RSVDO: Reserved
7	0h RW	Receiver FIFO Error Bit (RFE): This bit is only relevant when FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. <ul style="list-style-type: none"> 0 = no error in RX FIFO 1 = error in RX FIFO This bit is cleared when the LSR is read, the character with the error is at the top of the receiver FIFO, and there are no subsequent errors in the FIFO. Reset Value: 0x0
6	1h RW	Transmitter Empty Bit (TEMT): If FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1
5	1h RW	Transmit Holding Register Empty Bit (THRE): If THRE mode is disabled (IER[7] set to zero), this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE mode is enabled and and FIFOs enabled (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. Reset Value: 0x1
4	0h RW	Break Interrupt Bit (BI): This is used to indicate the detection of a break sequence on the serial input data. If in UART mode it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.
3	0h RW	Framing Error Bit (FE): This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). <ul style="list-style-type: none"> 0 = no framing error 1 = framing error Reading the LSR clears the FE bit. Reset Value: 0x0
2	0h RW	Parity Error Bit (PE): This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). <ul style="list-style-type: none"> 0 = no parity error 1 = parity error Reading the LSR clears the PE bit. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the DW_apb_uart is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] = 1), the rts_n output is held inactive-high while the value of this location is internally looped back to an input. Reset Value: 0x0

27.8.33 Shadow Break Control Register (SBCR)—Offset 90h

This is a shadow register for the Break bit (LCR[6]), this can be used to remove the burden of having to performing a read modify write on the LCR. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared.

28 SIO – Pulse Width Modulation (PWM)

The Pulse Width Modulation block allows control the frequency and duty cycle of an output signal. The SoC has 2 instances of the PWM interface.

28.1 Signal Descriptions

Please see [Chapter 2, “Physical Interfaces”](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

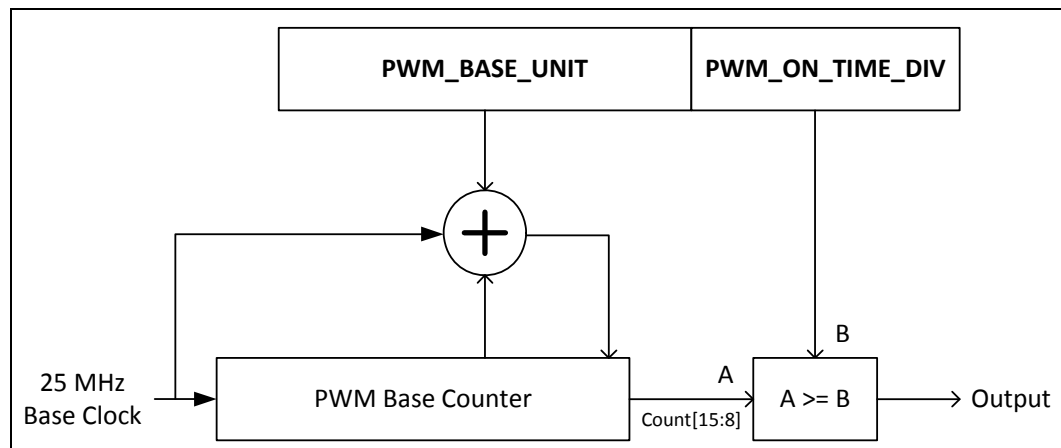

Figure 130. PWM Signals

Signal Name	Direction Plat. Power	Description
SIO_PWM[0]	O V1P8S	Pulse Width Modulation output 0.
SIO_PWM[1]	O V1P8S	Pulse Width Modulation output 1.

28.2 Features

The software controls the PWM block by updating the PWMCTRL register and setting the PWMCTRL.PWM_SW_UPDATE bit whenever a change in frequency or duty cycle of the PWM output signal is required. The PWM block applies the new settings at the start of the PWM output cycle and resets the PWMCTRL.PWM_SW_UPDATE bit. The SoC uses a 25 MHz base clock rate for the PWM counter. See [Figure 131](#) for PWM block diagram:

Figure 131. PWM Block Diagram

There are two controls of the PWM output:

- **Frequency** is controlled by the PWMCTRL.PWM_BASE_UNIT register. The PWMCTRL.PWM_BASE_UNIT value is added to the 16 bit PWM counter every base clock cycle. The counter roll-over/overflow marks the start of a new cycle and resets the counter to the value in PWMCTRL.PWM_BASE_UNIT.
- **Duty Cycle** is controlled by the PWMCTRL.PWM_ON_TIME_DIVISOR setting (0 to 255). When the 16 bit PWM counter is less than PWM_ON_TIME_DIVISOR * 256, the PWM output is low (0). When the 16 bit PWM counter is equal to or greater than PWM_ON_TIME_DIVISOR * 256, the PWM output is high (1).

The PWM block is clocked by the 25 MHz oscillator clock. The output frequency can be estimated with the equation:

- Target frequency = $25 \text{ MHz} / \text{CEILING}(65536/\text{PWM_BASE_UNIT})$
 Note that the larger the value of base_unit, the larger the error that the PWM output frequency will have with respect to the equation above. For example any $\text{Base_unit_value}/256 > 128$ will result in 12.5 MHz max frequency. Any value between 86 and 128 will result in 8.33 MHz output frequency. And accordingly the larger the base_unit value the smaller duty cycle resolution. Maximum duty cycle resolution is 8 bits.

[Table 281](#) illustrates the output frequency and duty-cycle resolution for different settings of the base_unit_value (when using 25 MHz oscillator clock).

Table 281. Example PWM Output Frequency and Resolution

Target Frequency	Base Unit Value Register	Base 25 MHz Cycle Count	Duty Cycle Resolution
12.5 MHz	$\geq 128 * 256$	1	no resolution
1.07 MHz	$11 * 256$	23	<8 bit resolution
488 kHz	$5 * 256$	51	<8 bit resolution
97.6 kHz	$1 * 256$	256	8 resolution
48.4 kHz	$0.5 * 256$	512	≥ 8 bit resolution
0	0	0	Flat 0 output

28.3 Use

28.3.1 PWM Programming Sequence

For first time activation, follow sequence:

1. Program the counter value PWMCTRL.PWM_BASE_UNIT and PWMCTRL.PWM_ON_TIME_DIVISOR
2. Set the PWMCTRL.PWM_SW_UPDATE bit
3. Enable PWM output by setting the PWMCTRL.PWM_ENABLE bit

For update on the fly, follow sequence:

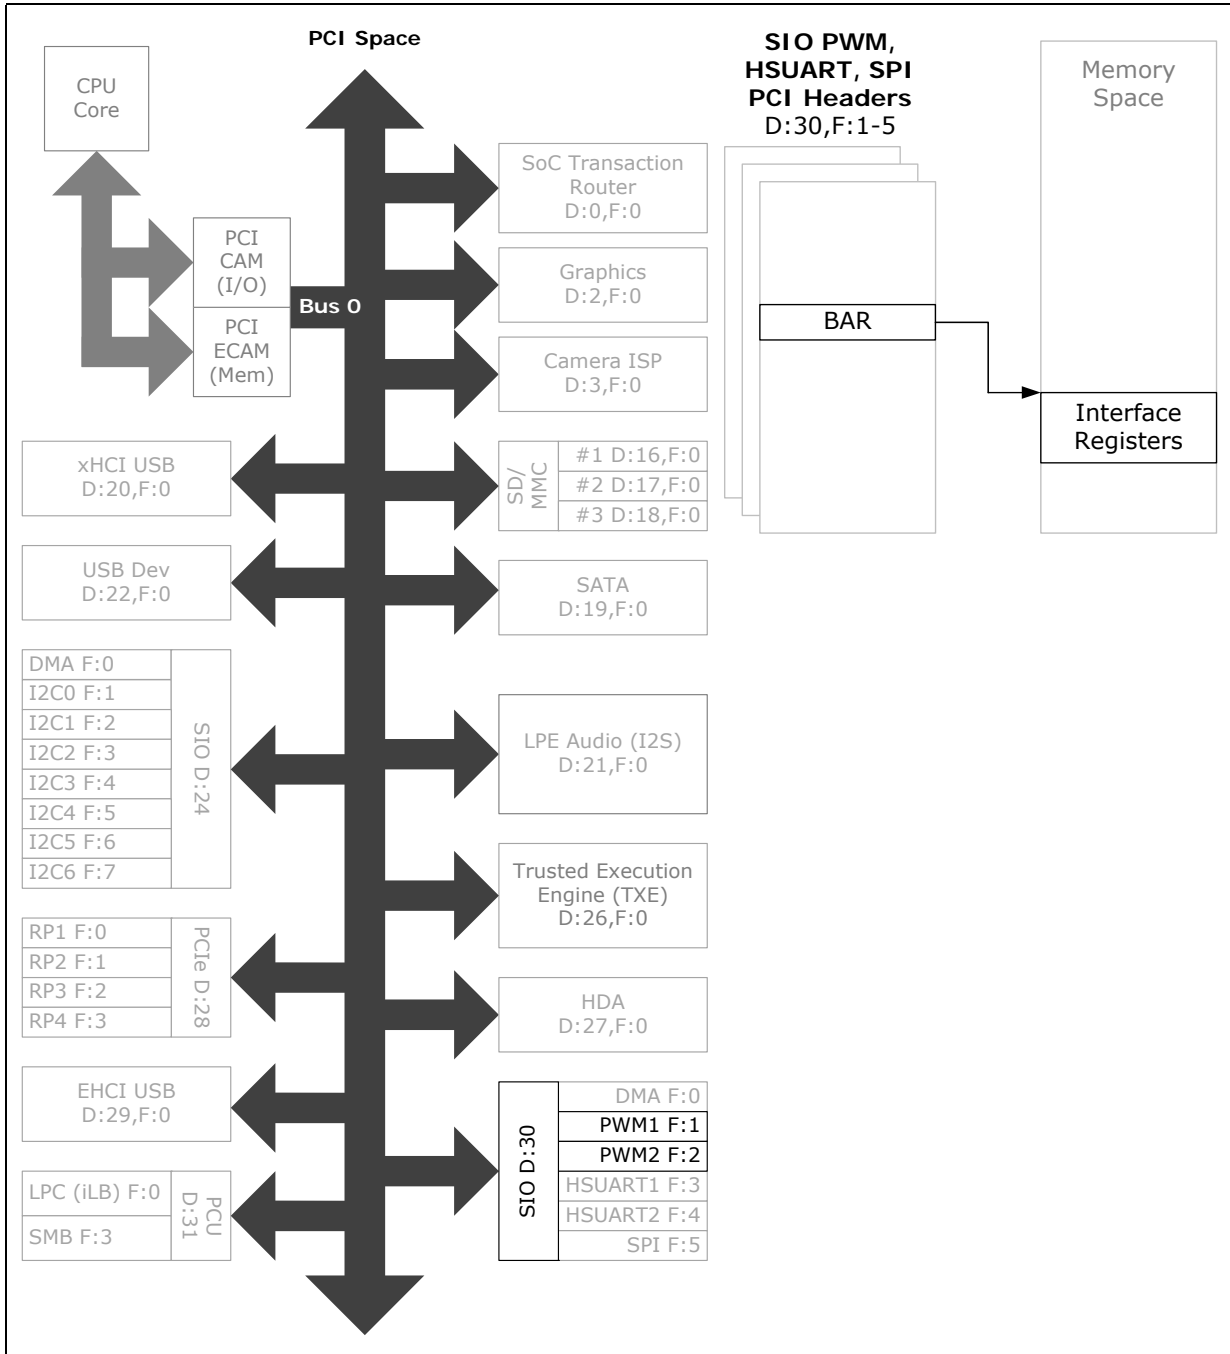

1. Program the counter value PWMCTRL.PWM_BASE_UNIT and PWMCTRL.PWM_ON_TIME_DIVISOR
2. Set the update bit PWMCTRL.PWM_SW_UPDATE

28.4 Register Map

Default: 00000000h

Bit Range	Default & Access	Field Name (ID): Description
31:16	0000h RW/O	Subsystem ID (SUBSYSTEMID): This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	Subsystem Vendor ID (SUBSYSTEMVENDORID): This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

28.5.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register

29	0h RW/1C	Received Master Abort (RMA): If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	Received Target Abort (RTA): If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	STA: Reserved.
26:21	00h RO	Reserved1: Reserved.
20	1h RO	Capabilities List (CAPLIST): Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	Interrupt Status (INTR_STATUS): This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	Reserved2: Reserved.
15:11	00h RO	Reserved3: Reserved.
10	0h RW	Interrupt Disable (INTR_DISABLE): Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	Reserved4: Reserved.
8	0h RW	SERR# Enable (SERR_ENABLE): If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.
7:3	00h RO	Reserved5: Reserved.
2	0h RW	Bus Master Enable (BME): If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.

Bit Range	Default & Access	Field Name (ID): Description
1	0h RW	Memory Space Enable (MSE): This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.

CLASS_CODES							RID	

Bit Range	Default & Access	Field Name (ID): Description
31:8	000000h RO	Class Code (CLASS_CODES): The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	Revision ID (RID): Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

29 Platform Controller Unit (PCU) Overview

The Platform Controller Unit (PCU) is a collection of HW blocks that are critical for implementing a Windows* compatible platform. These HW blocks include:

- PCU – Power Management Controller (PMC)
- PCU – Serial Peripheral Interface (SPI)
 - For boot FW and system configuration data Flash storage
- PCU – Universal Asynchronous Receiver/Transmitter (UART)PCU – System Management Bus (SMBus)
- PCU – Intel® Legacy Block (iLB) Overview

The PCU also implements some high level configuration features for BIOS/EFI boot.

29.1 Features

The key features of the individual blocks are as follows:

- Universal Asynchronous Receiver/Transmitter (UART)
 - 16550 controller compliant
 - Reduced Signal Count: TX and RX only
 - COM1 interface
- Serial Peripheral Interface (SPI)
 - For one or two SPI Flash, of up to 16MB size each, only. No other SPI peripherals are supported.
 - Stores boot FW and system configuration data

- Supports frequencies of 20 MHz, 33MHz and 50MHz.
- Power Management Controller (PMC)
 - Controls many of the power management features present in the SoC.
- Intel Legacy Block (iLB)
 - Supports legacy PC platform features
 - Sub-blocks include LPC, GPIO, 8259 PIC, IO-APIC, 8254 timers, HPET timers and the RTC.

30 PCU – Power Management Controller (PMC)

The Power Management Controller (PMC) controls many of the power management features present in the SoC.

30.1 Signal Descriptions

Please see [Chapter 2, "Physical Interfaces"](#) for additional details.

The signal description table has the following headings:

- **Signal Name:** The name of the signal/pin
- **Direction:** The buffer direction can be either input, output, or I/O (bidirectional)
- **Platform Power:** The reference power plane.
- **Description:** A brief explanation of the signal’s function

Table 287. PMC Signals (Sheet 1 of 3)

Signal Name	Direction Plat. Power	Description
PMC_ACPRESENT	I V1P8A	AC Present: This input pin indicates when the platform is plugged into AC power.
PMC_BATLOW#	I V1P8A	Battery Low: An input from the battery to indicate that there is insufficient power to boot the system. Assertion will prevent wake from the S5 state. This signal can also be enabled to cause an SMI# when asserted. In configurations without a battery, this signal should be tied high to V1P8_S5.

Table 287. PMC Signals (Sheet 2 of 3)

Signal Name	Direction Plat. Power	Description
PMC_CORE_PWROK	I VRTC	Core Power OK: When asserted, this signal is an indication to the SoC that all of its core power rails have been stable for 10 ms. It can be driven asynchronously. When it is negated, the SoC asserts PMC_PLTRST#. NOTE: It is required that the power rails associated with PCI Express (typically the 3.3V, 5V, and 12V core well rails) have been valid for 99 ms prior to PMC_CORE_PWROK assertion in order to comply with the 100 ms T_{PVPERL} PCI Express 2.0 specification on PMC_PLTRST# deassertion. NOTE: PMC_CORE_PWROK must not glitch, even if PMC_RSMRST# is low.
PMC_PLTRST#	O V1P8A	Platform Reset: The SoC asserts this signal to reset devices on the platform. The SoC asserts the signal during power-up and when software initiates a reset sequence through the Reset Control (RST_CNT) register when RST_CNT.sys_rst=1b.
PMC_PWRBTN#	I V1P8A	Power Button: The signal will cause SCI to indicate a system request to go to a sleep state. If the system is already in a sleep state, this signal will cause a wake event. If the signal is pressed for more than 4 seconds, this will cause an unconditional transition (power button override) to the S5 state. Override will occur even if the system is in the S3 & S4 states. This signal has an internal pull-up resistor and has an internal ~16 ms de-bounce on the input.
PMC_RSMRST#	I VRTC	Resume Well Reset: Used for resetting the resume well. An external RC circuit is required to guarantee that the resume well power is valid prior to this signal going high.
PMC_RSTBTN#	I V1P8S	System Reset: This signal forces an internal reset after being debounced (~16 ms).
PMC_SLP_S3#	O V1P8A	S3 Sleep Control: This signal is for power plane control. It can be used to control system power when it is in a S3 (Suspend To RAM), S4 (Suspend to Disk), or S5 (Soft Off) states.
PMC_SLP_S4#	O V1P8A	S4 Sleep Control: This signal is for power plane control. It can be used to control system power when it is in a S4 (Suspend to Disk) or S5 (Soft Off) state.
PMC_SUS_STAT#	O V1P8A	Suspend Status: This signal is asserted by the SoC to indicate that the system will be entering a low power state soon. This can be monitored by devices with memory that need to switch from normal refresh to suspend refresh mode. It can also be used by other peripherals as an indication that they should isolate their outputs that may be going to powered-off planes. <i>This signal is muxed and may be used by other functions.</i>

Table 287. PMC Signals (Sheet 3 of 3)

Signal Name	Direction Plat. Power	Description
PMC_SUSCLK	O V1P8A	Suspend Clock: This 32 kHz clock is an output of the RTC generator circuit for use by other chips for refresh clock. <i>This signal is muxed and may be used by other functions.</i>
PMC_SUSPWRDNACK	O V1P8A	Suspend Power Down Acknowledge: Asserted by the SoC on S0 to S4/5 transition when it does not require its Suspend well to be powered. This pin requires a pull-up to UNCORE_V1P8_G3. <i>This signal is muxed and may be used by other functions.</i>
PMC_WAKE_PCIE[3:0]#	I V1P8A	PCI Express* Port [3:0] Wake Event: Sideband wake signal on PCI Express asserted by a component requesting wake up. <i>This signal is muxed and may be used by other functions.</i>
PMC_PLT_CLK[5:0]	O V1P8S	Platform Clocks: Configurable single ended clocks, configurable to 25 MHz. <i>This signal is muxed and may be used by other functions.</i>

30.2 Features

30.2.1 Sx-G3-Sx, Handling Power Failures

Depending on when the power failure occurs and how the system is designed, different transitions could occur due to a power failure.

The GEN_PMCON1.AG3E bit provides the ability to program whether or not the system should boot once power returns after a power loss event. If the policy is to not boot, the system remains in an S5 state (unless previously in S4). There are only two possible events that will wake the system after a power failure.

- **PMC_PWRBTN#:** PMC_PWRBTN# is always enabled as a wake event. When RSMRST# is low (G3 state), the PM1_STS_EN.PWRBTN_STS bit is reset. When the SoC exits G3 after power returns (PMC_RSMRST# goes high), the PMC_PWRBTN# signal is already high (because the suspend plane goes high before PMC_RSMRST# goes high) and the PM1_STS_EN.PWRBTN_STS bit is 0b.
- **RTC Alarm:** The PM1_STS_EN.RTC_EN bit is in the RTC well and is preserved after a power loss. Like PM1_STS_EN.PWRBTN_STS the PM1_STS_EN.RTC_STS bit is cleared when PMC_RSMRST# goes low.

The SoC monitors both PMC_CORE_PWROK and PMC_RSMRST# to detect for power failures. If PMC_CORE_PWROK goes low, the GEN_PMCON1.PWR_FLR bit is set. If PMC_RSMRST# goes low, GEN_PMCON1.SUS_PWR_FLR is set.

Table 288. Transitions Due to Power Failure

State at Power Failure	GEN_PMCON1.AG3E bit	Transition When Power Returns
S0, S3	1	S5
	0	S0
S4	1	S4
	0	S0
S5	1	S5
	0	S0

30.2.2 Event Input Signals and Their Usage

The SoC has various input signals that trigger specific events. This section describes those signals and how they should be used.

30.2.3 PCI Express* WAKE# Signal and PME Event Message

PCI Express ports can wake the platform from any sleep state (S3, S4, or S5) using the PMC_WAKE_PCIE[3:0]# pins.

Note: PMC_WAKE_PCIE[3:0]# functionality is disabled by setting PM1_STS_EN.PCIEXP_WAKE_DIS to 1b.

PCI Express ports have the ability to cause PME using messages. When a PME message is received, the SoC will set the GPE0a_STS.PCI_EXP_STS bit.

30.2.3.1 PMC_PWRBTN# (Power Button)

The PMC_PWRBTN# signal operates as a “Fixed Power Button” as described in the Advanced Configuration and Power Interface specification. The signal has a 16 ms debounce on the input. The state transition descriptions are included in [Table 289](#). Note that the transitions start as soon as the PMC_PWRBTN# is pressed (but after the debounce logic), and does not depend on when the power button is released.

Note: During the time that the PMC_SLP_S4# signal is stretched for the minimum assertion width (if enabled), the power button is not a wake event. Refer to note below for more details.

Table 289. Transitions Due to Power Button

Present State	Event	Transition/Action	Comment
S0/Cx	PMC_PWRBTN# goes low	SCI generated (depending on PM1_CNT.SCI_EN and PM1_STS_EN.PWRBTN_EN)	Software typically initiates a Sleep state
S3-S4/S5	PMC_PWRBTN# goes low	Wake Event. Transitions to S0 state	Standard wakeup
G3	PMC_PWRBTN# pressed	None	No effect since no power Not latched nor detected
S0, S3-S4	PMC_PWRBTN# held low for at least 4 consecutive seconds	Unconditional transition to S5 state	No dependence on processor or any other subsystem

Power Button Override Function

If PMC_PWRBTN# is observed active for at least four consecutive seconds, the state machine should unconditionally transition to the S5 state, regardless of present state (S0-S4), even if the PMC_CORE_PWROK is not active. In this case, the transition to the G2/S5 state should not depend on any particular response from the processor nor any similar dependency from any other subsystem.

The PMC_PWRBTN# status is readable to check if the button is currently being pressed or has been released. The status is taken after the de-bounce, and is readable using the GEN_PMCON2.PWRBTN_LVL bit.

Note: The 4-second PMC_PWRBTN# assertion should only be used if a system lock-up has occurred. The 4-second timer starts counting when the SoC is in a S0 state. If the PMC_PWRBTN# signal is asserted and held active when the system is in a suspend state (S3-S4), the assertion causes a wake event. Once the system has resumed to the S0 state, the 4-second timer starts.

Note: During the time that the SLP_S4# signal is stretched for the minimum assertion width (if enabled by GEN_PMCON1.S4ASE), the power button is not a wake event. As a result, it is conceivable that the user will press and continue to hold the power button waiting for the system to awake. Since a 4-second press of the power button is already defined as an unconditional power down, the power button timer will be forced to inactive while the power-cycle timer is in progress. Once the power-cycle timer has expired, the power button awakes the system. Once the minimum PMC_SLP_S4# power cycle expires, the power button must be pressed for another 4 to 5 seconds to create the override condition to S5.

30.2.3.2 Sleep Button

The Advanced Configuration and Power Interface specification defines an optional sleep button. It differs from the power button in that it only is a request to go from S0 to S3–S4 (not S5). Also, in an S5 state, the power button can wake the system, but the sleep button cannot.

Although the SoC does not include a specific signal designated as a sleep button, one of the GPIO signals can be used to create a “Control Method” sleep button. See the Advanced Configuration and Power Interface specification for implementation details.

30.2.3.3 PME_B0 (PCI Power Management Event Bus 0)

The GPE0a_STS.PME_B0_STS bit exists to implement PME#-like functionality for any internal device on Bus 0 with PCI power management capabilities.

30.2.3.4 PMC_RSTBTN# Signal

When the PMC_RSTBTN# pin is detected as active after the 16 ms debounce logic, the SoC attempts to perform a “graceful” reset, by waiting for the relevant internal devices to signal their idleness. If all devices are idle when the pin is detected active, the reset occurs immediately; otherwise, a counter starts. If at any point during the count all devices go idle the reset occurs. If the counter expires and any device is still active, a reset is forced upon the system even though activity is still occurring.

Once the reset is asserted, it remains asserted for 5 to 6 ms regardless of whether the PMC_RSTBTN# input remains asserted or not. It cannot occur again until PMC_RSTBTN# has been detected inactive after the debounce logic, and the system is back to a full S0 state with PMC_PLTRST# inactive. Note that if RST_CNT.FULL_RST is set then PMC_RSTBTN# will result in a Host Reset with Power Cycle.

30.2.4 System Power Planes

The system has several independent power planes, as described in Table 290. Note that when a particular power plane is shut off, it should go to a 0 V level.

Table 290. System Power Planes (Sheet 1 of 2)

Plane	Controlled By	Description
CPU	PMC_SLP_S3#	The SLP_S3# signal can be used to cut the CORE_VCC_S3 rail completely.
Main	PMC_SLP_S3#	When SLP_S3# goes active, power can be shut off to any circuit not required to wake the system from the S3 state. Since the S3 state requires that the memory context be preserved, power must be retained to the main memory. Devices on LPC bus, PCI-Express, and SATA will typically be shut when the Main power plane is shut, although they may have small subsections powered.

Table 290. System Power Planes (Sheet 2 of 2)

Plane	Controlled By	Description
Devices and Memory	PMC_SLP_S4#	When PMC_SLP_S4# goes active, power can be shut off to any circuit not required to wake the system from the S4/S5. Since the memory context does not need to be preserved in the S4/S5 state, the power to the memory can also be shut down. S4 and S5 requests are treated the same so no PMC_SLP_S5# signal is implemented.
Devices	Implementation Specific	Individual subsystems may have their own power plane. For example, GPIO signals may be used to control the power to disk drives, audio amplifiers, or the display screen.
Suspend	PMC_SUSPWRDNA CK	The suspend power planes are generally left on whenever the system has a charged main battery or is plugged in to AC power, even in S4/5. In some cases, it may be preferable to disable the suspend power planes in S4/S5 states to save additional power. This requires some external logic (such as an embedded controller) to decide on the appropriate power plane control actions and ensure that a wake event is still possible (such as the power button).

30.2.4.1 Power Plane Control with PMC_SLP_S3#, PMC_SLP_S4#

The PMC_SLP_S3# output signal can be used to cut power to the system core supply, since it only goes active for the Suspend-to-RAM state (typically mapped to ACPI S3). Power must be maintained to the SoC suspend well, and to any other circuits that need to generate wake signals from the Suspend-to-RAM state. During S3 (Suspend-to-RAM) all signals attached to powered down plans will be tri-stated or driven low, unless they are pulled using a pull-up resistor. Cutting power to the core may be done using the power supply, or by external FETs on the motherboard.

The PMC_SLP_S4# output signal can be used to cut power to the system core supply, as well as power to the system memory, since the context of the system is saved on the disk. Cutting power to the memory may be done using the power supply, or by external FETs on the motherboard.

30.2.4.2 PMC_SLP_S4# and Suspend-To-RAM Sequencing

The PMC_SLP_S4# signal should be used to remove power to system memory. The PMC_SLP_S4# logic in the SoC provides a mechanism to fully cycle the power to the DRAM and/or detect if the power is not cycled for a minimum time.

Note: To use the minimum DRAM power-down feature that is enabled by the GEN_PMCON1.S4ASE bit, the DRAM power must be controlled by the PMC_SLP_S4# signal.

30.2.4.3 PMC_CORE_PWROK Signal

When asserted, PMC_CORE_PWROK is an indication to the SoC that its core well power rails are powered and stable. PMC_CORE_PWROK can be driven asynchronously. When PMC_CORE_PWROK is low, the SoC asynchronously asserts PMC_PLTRST#. PMC_CORE_PWROK must not glitch, even if PMC_RSMRST# is low.

It is required that the power rails associated with PCI Express have been valid for 99 ms prior to PWROK assertion in order to comply with the 100 ms T_{PVPERL} PCI Express 2.0 specification on PMC_PLTRST# deassertion.

Note: PMC_RSTBTN# is recommended for implementing the system reset button. This saves external logic that is needed if the PMC_CORE_PWROK input is used. Additionally, it allows for better handling of the processor resets and avoids improperly reporting power failures.

30.2.4.4 PMC_BATLOW# (Battery Low)

The PMC_BATLOW# input can inhibit waking from S3, S4, and S5 states if there is not sufficient power. It also causes an SMI if the system is already in an S0 state.

30.2.5 SMI#/SCI Generation

Upon any enabled SMI event taking place while the SMI_EN.EOS bit is set, the SoC will clear the EOS bit and assert SMI to the CPU core, which will cause it to enter SMM space. SMI assertion is performed using a Virtual Legacy Wire (VLW) message. Prior system generations (those based upon legacy processors) used an actual SMI# pin.

Once the SMI message has been delivered, the SoC takes no action on behalf of active SMI events until Host software sets the End of SMI (EOS) bit. At that point, if any SMI events are still active, the SoC will send another SMI message.

The SCI is a level-mode interrupt that is typically handled by an ACPI-aware operating system. In non-APIC systems (which is the default), the SCI IRQ is routed to one of the 8259 interrupts (IRQ 9, 10, or 11). The 8259 interrupt controller must be programmed to level mode for that interrupt.

In systems using the APIC, the SCI can be routed to interrupts IRQs[11:9] or IRQs[23:20]. The interrupt polarity changes depending on whether it is on an interrupt shareable with a PIRQ or not. The interrupt remains asserted until all SCI sources are removed.

Table 291 shows which events can cause an SMI and SCI. Note that some events can be programmed to cause either an SMI or SCI. The usage of the event for SCI (instead of SMI) is typically associated with an ACPI-based system. Each SMI or SCI source has a corresponding enable and status bit.

NOTES:

- Most of the status bits (except otherwise is noted) are set according to event occurrence regardless to the enable bit.
- GPIO status bits are set only if enable criteria is true. GPIO_ROUT[n]=10b & GPE0a_EN.x_GPIO_EN[n] for GPE0a_STS.x_GPIO_STS[n] (SCI). GPIO_ROUT[n]=01b & ALT_GPIO_SMI.x_GPIO_SMI_EN[n]=1b for ALT_GPIO_SMI.x_GPIO_SMI_STS[n] (SMI).
- When power button override occurs, the system will transition immediately to S5. The SCI will only occur after the next wake to S0 if the residual status bit (PM1_STS_EN.PWRBTNOR_STS) is not cleared prior to setting PM1_CNT.SCI_EN.
- PM1_STS_EN.GBL_STS being set will cause an SCI, even if the PM1_CNT.SCI_EN bit is not set. Software must take great care not to set the SMI_ENBIOS_RLS bit (which causes PM1_STS_EN.GBL_STS to be set) if the SCI handler is not in place.
- No enable bits for these SCI/SMI messages in the PMC. Enable capability should be implemented in the source unit.
- Sync SMI has the same message opcode toward T-Unit. Special treatment regarding this Sync SMI is holding completion to host till SYNC_SMI_ACK message is received from T-Unit.
- Sync SMI has the same message opcode toward T-Unit. Special treatment regarding this Sync SMI is holding the SSMI_ACK message to iLB till SYNC_SMI_ACK message is received from T-Unit.
- The G-Unit is an internal functional sub-block which forms part of the graphics functional block.
- The GPE0a_STS.CORE_GPIO_STS[31:24] & GPE0a_EN.CORE_GPIO_EN[31:24] register bits correspond to GPIO_S0_SC[7:0]. GPE0a_STS.SUS_GPIO_STS[23:16] & GPE0a_EN.SUS_GPIO_EN[23:16] correspond to GPIO_S5[7:0].
- The ALT_GPIO_SMI.CORE_GPIO_SMI_STS[31:24] & ALT_GPIO_SMI.CORE_GPIO_SMI_EN[15:8] register bits correspond to GPIO_S0_SC[7:0]. ALT_GPIO_SMI.SUS_GPIO_SMI_STS[23:16] & ALT_GPIO_SMI.SUS_GPIO_SMI_EN[7:0] correspond to GPIO_S5[7:0].

30.2.6 Platform Clock Support

The SoC supports up to 6 clocks (PMC_PLT_CLK[5:0]) with a frequency of either 19.2 MHz or 25 MHz. These clocks are available for general system use, where appropriate and each have Control & Frequency register fields associated with them.

Note: [Intel recommends 25 MHz. 19.2 MHz is not validated.](#)

30.2.7 INIT# (Initialization) Generation

The INIT# functionality is implemented as a 'virtual wire' internal to the SoC rather than a discrete signal. This virtual wire is asserted based on any one of the events described in below table. When any of these events occur, INIT# is asserted for 16 PCI clocks and then driven high.

INIT#, when asserted, resets integer registers inside the CPU cores without affecting its internal caches or floating-point registers. The cores then begin execution at the power on Reset vector configured during power on configuration.

Table 292. INIT# Assertion Causes

Cause	Comment
PORT92.INIT_NOW transitions from 0b to 1b.	
RST_CNT.SYS_RST = 0b and RST_CNT.RST_CPU transitions from 0b to 1b	

30.3 USB Per-Port Register Write Control

The PMC contains the UPRWC.USB_PER_PORT_WE (USB Per-Port Registers Write Enable) bit. When this bit is written from 0b to 1b, the UPRWC.WE_STS (Write Enable Status) bit is asserted. This transaction initiates sync-SMI if the UPRWC.WE_SMIEN (Write Enable SMI Enable) bit and the SMI_EN.USB_IS_SMI_EN (USB Intel Specific SMI Enable) bit are set to 1b.

30.6.1 PRSTS - Power and Reset Status (PRSTS)—Offset 0h

Bits in this register only need to be valid for reading when the Main power well is up. However, since some of the events may initially be detected while the Main power well is down, they are marked as suspend well bits. All suspend well bits in this register are reset by global reset#.

31:24	0b RO	Power Management Controller Product ID (PMC_PRODID) (pmc_prodid): This field communicates the Product Family of the power management functionality
23:16	0b RO	Power Management Controller Revision ID (PMC_REVID) (pmc_revid): This field communicates the implementation revision of the power management functionality.
15	0b RW	PMC Watchdog Timer Status (PMC_WDT_STS) (pmc_wdt_sts): This bit will be set to '1' when the PMC Watch Dog Timer triggers a reset. It will be cleared by a write of '1' by software.
14:12	0b RO	reserved: Reserved.
11	0b RO	Code Copied Over Status (CODE_COPIED_STS) (code_copied_sts): The SOC sets this bit when PMC code is successfully authenticated and loaded from the flash
10	0b RO	reserved (reserved1): Reserved.
9	0b RO	Code Load Timeout Status (CODE_LOAD_TO) (code_load_to): The SOC sets this bit if the loading function fails to complete within a reasonable time limit. This bit remains valid after a PMC Code load is attempted until the next global reset
8	0b RO	PMC Operational Status (PMC_OP_STS) (pmc_op_sts): The SOC sets this bit when the PMC becomes operational after completing the Code Load. BIOS must wait for this bit to be set before performing resets or sleep events. This bit remains valid after a PMC Code load until the next global reset
7	0b RW	SEC Watch Dog Timer Status (SEC_GBLRST_STS) (sec_gblrst_sts): This bit will be set to '1' when the SEC FW triggers a reset. It will be cleared by a write of '1' by software.
6	0b RW	SEC Watch Dog Timer Status (SEC_WDT_STS) (sec_wdt_sts): This bit will be set to '1' when the SEC Watch Dog Timer triggers a reset. It will be cleared by a write of '1' by software.
5	0b RW	Wake On LAN Override Wake Status (WOL_OVR_WK_STS) (wol_ovr_wk_sts): This bit gets set when integrated LAN Signals a Power Management Event AND the system is in S5. BIOS can read this status bit to determine this wake source. Software clears this bit by writing a 1 to it.
4	0b RW	PMC_HOST_WAKE_STS (PMC_HOST_WAKE_STS) (pmc_host_wake_sts): The SOC Power Management Controller sets this bit if it wakes the host for reasons other than typical host-visible wake events. This status bit provides information to BIOS that the PMC caused the wake.
3:0	0b RO	reserved2: Reserved.

30.6.2 PM_CFG - Power Management Configuration (PMC_CFG)—Offset 8h

This register contains misc. fields used to configure the SOC's power management behavior.

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

PMC_CFG: [PMC_BASE_ADDRESS] + 8h

PMC_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)

PMC_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 44h

Default: 00000000h

Bit Range	Default & Access	Description
31:6	0b RO	reserved: Reserved.
5	0b RW	Shutdown Policy Select (SPS) (sps): When cleared (default) the SOC will drive INIT# in response to the shutdown Message. When set to 1, SOC will treat the shutdown message similar to receiving a CF9h I/O write, and will drive PMU_PLTRST active. . BIOS guide note: This register is reset any time PMU_PLTRST asserts.
4	0b RW	No Reboot (NO_REBOOT) (no_reboot): This bit is set when the No Reboot strap is sampled high on COREPWROK. This bit may be set or cleared by software if the strap is sampled low but may not override the strap when it indicates No Reboot. When set, the TCO timer will count down and generate the SMI# on the first timeout, but will not reboot on the second timeout.
3	0b RW	S1/3/4/5 Entry Timeout Enable (SX_ENT_TO_EN) (sx_ent_to_en): This policy bit determines whether the SOC will apply a timeout to the S1/S3/S4/S5 entry flow. If this timeout is enabled and the entry flow appears to be hung, the SOC will trigger a straight-to-S5 global reset. Encodings: 0: Timeout disabled (default) 1: Timeout enabled reset_type=RSMRST_B
2	0b RO	reserved (reserved2): Reserved.
1:0	0b RW	Timing t581 (TIMING_T581) (timing_t581): This field configures the t581 timing involved in the power down flow (CPU Power Good indication inactive to PLL Enable inactive). Encodings (all min timings): 00: 10 us (default) 01: 100 us 10: 1 ms 11: 10 ms reset_type=Resume Well Reset#

30.6.3 VLV_PM_STS - VLV Power Management Status (VLV_PM_STS)—Offset Ch

This register contains misc. fields used to record events pertaining to SOC power management. Unless otherwise indicated, all RWC bits are cleared with a write of 1 by software.

20	0b RO	PMC Message 1 Full Status (PMC_MSG_1_FULL_STS) (pmc_msg_1_full_sts): This bit gets set to 1b automatically when the Message to PMC 1 register is written. The PMC clears this bit when it has serviced the message. Host software should poll this bit until it returns a 0b to avoid overwriting the previous message data before the PMC could service it.
19:9	0b RO	reserved1: Reserved.
8	0b RO	Code Requested (CODE_REQ) (code_req): PMC will set this bit when SEC unit requests exclusion from power flows
7:3	0b RO	reserved2: Reserved.
2	0b RW	Host Partition Reset Entry Timeout (HPR_ENT_TO) (hpr_ent_to): This bit is set to '1' to record that a global reset was triggered by a timeout during Host partition reset entry sequence.
1	0b RW	S3/4/5 Entry Timeout (SX_ENT_TO) (sx_ent_to): This bit is set to '1' to record that a global reset was triggered by a timeout during an S3, S4, or S5 entry sequence.
0	0b RO	reserved3: Reserved.

Bit Range	Default & Access	Description
23	0b RW	DRAM Initialization Scratchpad Bit (DISB) (disb) : This bit does not effect hardware functionality in any way. It is provided as a scratchpad bit that is maintained through main power well resets and CF9h-initiated resets. BIOS is expected to set this bit prior to starting the DRAM initialization sequence and to clear this bit after completing the DRAM initialization sequence. BIOS can detect that a DRAM initialization sequence was interrupted by a reset by reading this bit during the boot sequence. If the bit is 1, then the DRAM initialization was interrupted. This bit is reset by the assertion of the RSMRST_B pin.
22	0b RO	RSVDO : Reserved
21	0b RO	Memory Placed in Self-Refresh (MEM_SR) (mem_sr) : This bit will be set to 1 if DRAM should have remained powered and held in Self-Refresh through the last power state transition (i.e. the last time the system left S0). The scenarios where this should be the case are: - successful S3 entry and exit - successful Host partition reset without power cycle This bit will be cleared whenever the SOC begins a transition out of S0. Note: This bit should not be consulted upon wake from S1, as that state does not involve the same type of handshake or placing memory into Self-Refresh. It is assumed that software is already aware that memory context is not impacted by S1 and therefore does not need to check this bit. reset_type=global reset
20	0b RW	System Reset Status (SRS) (srs) : SOC sets this bit when the PMU_RESETBUTTON_B# button is pressed. BIOS is expected to read this bit and clear it if it is set. This bit is also reset by RSMRST_B and CF9h resets. reset_type=Resume Well Reset#
19	0b RW	CPU Thermal Trip Status (CTS) (cts) : This bit is set when the SOC thermal trip active while the system is in a valid state to honor the pin. This bit is also reset by RSMRST_B and CF9h resets. It is not reset by the shutdown and reboot associated with the thermal trip event. reset_type=Resume Well Reset#
18	0b RW	Minimum PMU_SLP_S4_B Assertion Width Violation Status (MS4V) (ms4v) : Hardware sets this bit when the PMU_SLP_S4_B assertion width is less than the time programmed in the PMU_SLP_S4_B Minimum Assertion Width field. The SOC begins the timer when PMU_SLP_S4_B pin is asserted during S4/S5 entry, or when the RSMRST_B input is deasserted during SUS well power-up. The status bit is cleared by software writing a 1 to the bit. Note that this bit is functional regardless of the value in the PMU_SLP_S4_B Assertion Stretch Enable and the Disable-SLP_X-Stretching-After-SUS-Power-Failure bits. This bit is reset by the assertion of the RSMRST_B pin, but can be set in some cases before the default value is readable. reset_type=RSMRST_B
17	0b RO	reserved3 : Reserved.
16	0b RW	COREPWROK Failure (PWR_FLR) (pwr_flr) : Intel SOC sets this bit any time COREPWROK goes low if the system was in an S0 or S1 state. The bit will be cleared only by software writing a 1 back to the bit or by SUS well power loss. reset_type=global reset
15	0b RW	PME B0 S5 Disable (PME_B0_S5_DIS) (pme_b0_s5_dis) : When set to '1', this bit blocks wake events from PME_B0_STS in S5, regardless of the state of PME_B0_EN. When cleared (default), wake events from PME_B0_STS are allowed in S5 if PME_B0_EN = '1'. Wakes from power states other than S5 are not affected by this policy bit. The net effect of setting PME_B0_S5_DIS = '1' is described by the truth table below: Y = Wake N = Don't wake B0 = PME_B0_EN OV = WOL Enable Override B0/OV S1/S3/S4 S5 00 N N 01 N Y (LAN only) 11 Y (all PME B0 sources) Y (LAN only) 10 Y (all PME B0 sources) N This bit is cleared by the SRTCST_B pin. reset_type=SRTCST_B
14	1b RW	SUS Well Power Failure (SUS_PWR_FLR) (sus_pwr_flr) : This bit is set to '1' whenever SUS well power is lost, as indicated by RSMRST_B assertion. Software writes a 1 to this bit to clear it. This bit is in the SUS well, and defaults to '1' based on RSMRST_B assertion (not cleared by any type of reset). Implementation Note: RSMRST_B is an asynchronous set term to this bit. reset_type=RSMRST_B

Bit Range	Default & Access	Description
13	0b RW	WOL Enable Override (WOL_EN_OVRD) (wol_en_ovrd): When this bit is set to 1, the integrated LAN is enabled to wake the system from S5 regardless of the value in the PME_B0_EN bit in the GPE0a_EN register. This allows the system BIOS to enable Wake-On-LAN regardless of the policies selected through the operating system. This bit is maintained in the RTC power well, therefore permitting WOL following a surprise power failure even in cases in which the system may have been running in S0 without the PME Enables set. (Note that the LAN NVRAM configuration must support WOL after SUS power loss.) When this bit is cleared to 0, the wake-on-LAN policies are determined by OS-visible bits. This bit has no effect on wakes from S1, S3, or S4. This bit is cleared by the SRTCST_B pin reset_type=SRTCST_B
12	0b RW	Disable SLP_X Stretching After SUS Well Power Up (DIS_SLP_X_STRCH_SUS_UP) (dis_slp_x_strch_sus_up): When this bit is set to 1, all SLP_* pin stretching is disabled when powering up after a SUS well power loss. When this bit is left at 0, SLP_* stretching will be performed after SUS power failure as enabled in various other fields. Note that if this bit is a 0, SLP_* stretch timers start on SUS well power up (the SOC has no ability to count stretch time while the SUS well is powered down). Setting this bit can therefore prevent long delays after SUS power loss which may be common in mobile platforms and in manufacturing flow testing, while still allowing for the full power cycling during S3, S4 and S5 states. If the platform guarantees minimum SUS power down residence in other ways, an additional SOC-induced delay is not needed or wanted. This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by the SRTCST_B pin.
11:10	0b RW	PMU_SLP_S3_B Minimum Assertion Width (SLP_S3_MIN_ASST_WDTH) (slp_s3_min_asst_wdth): This 2-bit value indicates the minimum assertion width of the PMU_SLP_S3_B signal to guarantee that the Main power supplies have been fully power-cycled. This value may be modified per platform depending on power supply capacitance, board capacitance, power failure detection circuits, etc. Settings are: 00: 60 usec 01: 1 ms 10: 50 ms 11: 2 sec This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by the RSMRST_B pin. reset_type=RSMRST_B
9	0b RW	General Reset Status (GEN_RST_STS) (gen_rst_sts): This bit is set by hardware whenever PMU_PLTRST asserts for any reason other than going into a software-entered sleep state (via PM1_CNT.SLP_EN write). This bit is an optional tool to help BIOS determine when a reset might have collided with a wake from a valid sleep state. A possible usage model would be to consult and then write a '1' to clear this bit during the boot flow before determining what action to take based on reading PM1_STS.WAK_STS = '1'. If GEN_RST_STS = '1', the cold reset boot path could be followed rather than the resume path, regardless of the setting of WAK_STS. This bit does not affect SOC operation in any way, and can therefore be left set if BIOS chooses not to use it. This bit is set by global reset. reset_type=global reset
8	0b RW	RTC_reserved (rtc_reserved): reset_type=SRTCST_B
7:6	0b RW	SWSMI Rate Select (SWSMI_RATESEL) (swsmi_rateSEL): This 2-bit value indicates when the SWSMI timer will time out. Valid values are: 00 1.5ms +/- 0.6ms 01 16ms +/- 4ms 10 32ms +/- 4ms 11 64ms +/- 4ms These bits are not cleared by any type of reset except SRTCST_B.
5:4	0b RW	PMU_SLP_S4_B Minimum Assertion Width (S4MAW) (s4maw): This 2-bit value indicates the minimum assertion width of the PMU_SLP_S4_B signal to guarantee that the DRAMs have been safely power-cycled. This value may be modified per platform depending on DRAM types, power supply capacitance, etc. Valid values are: - 11: 1 second - 10: 2 seconds - 01: 3 seconds - 00: 4 seconds This value is used in two ways: 1. If the PMU_SLP_S4_B assertion width is ever shorter than this time, a status bit is set for BIOS to read when S0 is entered 2. If enabled by bit 3 in this register, the hardware will prevent the PMU_SLP_S4_B signal from deasserting within this minimum time period after asserting. Note that the logic that measures this time is in the suspend power well. Therefore, when leaving a G3 state, the minimum time is measured from the deassertion of the internal suspend well reset (unless the Disable SLP_X Stretching After SUS Power Failure bit is set). This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. SRTCST_B forces this field to the conservative default state (00b). reset_type=SRTCST_B

Bit Range	Default & Access	Description
3	0b RW	PMU_SLP_S4_B Assertion Stretch Enable (S4ASE) (s4ase) : When set to 1, the PMU_SLP_S4_B pin will minimally assert for the time specified in bits 5:4 of this register. This bit is provided so that all DIMMs in the system can deterministically detect a power-cycle event for proper initialization. Note that there are behavioral changes that may be noticeable to the end-user when this bit is set. Resume times from S4 and S5 and power-up times from G3 may be delayed by several seconds. Cases in which this feature may not be desirable and therefore keeping the bit cleared are: - A customer decides the user confusion due to the hardware delay is a bigger issue than the potential DRAM issue - A customer decides the software status bit solution is adequate - A different DRAM type is used or the platform provides an external solution to solve the power-cycling issue - Validation regressions are impacted by the delay (especially after RSMRST_B deassertion) - Avoid potential resume time WHQL violations This bit is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by SRTCST_B.reset_type=SRTCST_B
2	1b RW	RTC_PWR_STS (RPS) (rps) : Intel SOC will set this bit to 1 when RTEST_B indicates a weak or missing battery. The bit will remain set until the software clears it by writing a 0 back to this bit position. This bit is not cleared by any type of reset. reset_type=RTEST_B
1	0b RO	reserved : Reserved.
0	0b RW	AFTERG3_EN (AG3E) (ag3e) : Determines what state to go to when power is reapplied after a power failure (G3 state). 0 = System will return to an S0 state (boot) after power is re-applied. 1 = System will return to the S5 state (except if it was in S4, in which case it will return to S4-like state). In the S5 state, the only enabled wake-up event is the Power Button or any enabled wake event that was preserved through the power failure. This bit is in the RTC well and is only cleared by SRTCST_B assertion. reset_type=SRTCST_B

30.6.14 S0ix control (S0IX_CTL)—Offset 44h

This register contains S0ix miscellaneous controls

Access Method

Type: Memory Mapped I/O Register
(Size: 32 bits)

S0IX_CTL: [PMC_BASE_ADDRESS] + 44h

PMC_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)

PMC_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 44h

Default: 00000050h

Bit Range	Default & Access	Description
19	0b RO	reserved (reserved1): Reserved.
18	0b RW	CF9h Without Resume Well Reset Enable (CWORWRE) (cworwre) : When this bit is set, a CF9h write of 6h or Eh will not cause internal Resume Well Reset (WrsmrstB) to be asserted and thus resume well logic will maintain its state. When this bit is cleared, CF9h write of 6h or Eh will also reset resume well logic. This bit is to be used when a second reset through CF9 write is desired upon power up or after resume from low power states. This bit has to be set prior to the write to CF9 register and has to be cleared upon completing the reset. Failing to do so prevents resume well registers from being reset in the future CF9 writes. reset_type=RSMRST_B
17:16	11b RW	MAX_SOIX (MAX_SOIX (max_s0ix)) : Indicated the maximum S0i state SOC can go

Bit Range	Default & Access	Description
31:0	0b RW	GPIO Rout (GPIO_ROUT) (gpio_rout) : Bits [15:0] determines GPIO SUS events rout. Bits [31:16] determines GPIO CORE events rout. Bits [1:0] determines GPIO SUS event 0. Bits [3:2] determines GPIO SUS event 1 and so on. Bits [17:16] determines GPIO CORE event 0. Bits [19:18] determines GPIO CORE event 1 and so on. If the corresponding GPIO is implemented and is set to an input, a '1' in the GP_LVL bit can be routed to cause an interrupt. If the GPIO is not set to an input, this field has no effect. * 00 No effect (or GPIO unimplemented), * 01 SMI# (if corresponding ALT_GPIO_SMI bit also set), * 10 SCI (if corresponding GPE0a_EN bit also set), * 11 Reserved If the system is in an S0-S5 state and if the GPE0a_EN bit is also set, then the GPIO can cause a Wake event, even if the GPIO is NOT routed to cause an interrupt. Exception: If the system is in S5 state due to a powerbutton override, then the GPIO's will not cause wake events. Note: Core well GPIO's are not capable of waking the system from sleep states where the core well is not powered.

3	0b RW	Full Reset (FULL_RST) (full_rst): When this bit is set to 1 and bit 1 is set to 1 (indicating Hard Reset, not Soft Reset), and the RST_CPU bit (bit 2) is written from 0 to 1, the PMC will do a full reset, including driving PMU_SLP_S3_B and PMU_SLP_S4_B active (low) for at least 3 (and no more than 5) seconds. When this bit is set, it also causes the full power cycle (PMU_SLP_S3/4_B assertion) in response to PMU_RESETBUTTON_B, COREPWOK, and Watchdog timer reset sources.
2	0b RW	Reset CPU (RST_CPU) (rst_cpu): This bit will cause either a hard or soft reset to the CPU depending on the state of the SYS_RST bit (bit 1 in this same register). The software will cause the reset by setting bit 2 from a 0 to a 1.
1	0b RW	System Reset (SYS_RST) (sys_rst): This bit determines the type of reset caused via RST_CPU (bit 2 of this register). If SYS_RST is 0 when RST_CPU goes from 0 to 1, then the PMC will force INIT# active for 16 PCI clocks. If SYS_RST is 1 when RST_CPU goes from 0 to 1, then the PMC will force PCI reset active for about 1 ms, however the PMU_SLP_S3_B and PMU_SLP_S4_B signals assertion is dependent on the value of the FULL_RST (bit3 of this register).

30	0b RW	PCI Express Wake Disable (PCIEXP_WAKE_DIS) (pciexp_wake_dis): This bit disables the inputs to the PCIEXP_WAKE_STS bit in the PM1 Status register from waking the system. Modification of this bit has no impact on the value of the PCIEXP_WAKE_STS bit. reset_type=Resume Well Reset#
29	0b RW	USB clockless Wake Enable (USB_CLKLESS_EN) (usb_clkless_en): This bit enables the inputs to the USB_CLKLESS_STS bit in the PM1 Status register to wake the system. Modification of this bit has no impact on the value of the USB_CLKLESS_STS bit. reset_type=Resume Well Reset#

26	0b RW	RTC Alarm Enable (RTC_EN) (rtc_en): This is the RTC alarm enable bit. It works in conjunction with the SCI_EN bit: RTC_EN SCI_EN Effect when RTC_STS is set 0 x No SMI# or SCI. If system was in S1-S5, no wake even occurs. 1 0 SMI#. If system was in S1-S5, then a wake event occurs before the SMI#. 1 1 SCI. If system was in S1-S5, then a wake event occurs before the SCI. Note: This bit needs to be backed by the RTC well to allow an RTC event to wake after a power failure. In addition to being reset by SRTCST_B assertion, PMC also clears this bit due to certain events: - Power button override - CPU thermal trip reset_type=SRTCST_B
25	0b RO	reserved6: Reserved.
24	0b RW	Power Button Enable (PWRBTN_EN) (pwrbtn_en): This bit is the power button enable. It works in conjunction with the SCI_EN bit: PWRBTN_EN SCI_EN Effect when PWRBTN_STS is set 0 x No SMI# or SCI. 1 0 SMI#. 1 1 SCI. NOTE: PWRBTN_EN has no effect on the PWRBTN_STS bit being set by the assertion of the power button. The Power Button is always enabled as a Wake event. reset_type=Resume Well Reset#
23:22	0b RO	reserved7: Reserved.
21	0b RW	Global Enable (GBL_EN) (gbl_en): The global enable bit. When both the GBL_EN and the GBL_STS are set, PMC generates an SCI. reset_type=PMU_PLTRST_B
20:17	0b RO	reserved8: Reserved.
16	0b RW	Timer Overflow Interrupt Enable (TMROF_EN) (tmrof_en): This is the timer overflow interrupt enable bit. It works in conjunction with the SCI_EN bit: TMROF_EN SCI_EN Effect when TMROF_STS is set 0 x No SMI# or SCI. . 1 0 SMI#. 1 1 SCI. reset_type=PMU_PLTRST_B
15	0b RW	Wake Status (WAK_STS) (wak_sts): This bit is set when the system is in one of the Sleep states (via the SLP_EN bit) and an enabled Wake event occurs. Upon setting this bit, the PMC will transition the system to the ON state. This bit can only be set by hardware and can only be cleared by writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. If a power failure occurs (such as removed batteries) without the SLP_EN bit set, the WAK_STS bit will not be set when the power returns if the AFTER_G3 bit is 0. If the AFTER_G3 bit is 1, then the WAK_STS bit will be set after waking from a power failure. If necessary, the BIOS can clear the WAK_STS bit in this case This is based on discussions with Microsoft. That behavior is not in the ACPI spec. reset_type=RSMRST_B

Bit Range	Default & Access	Description
14	0b RW	PCI Express Wake Status (PCIEXP_WAKE_STS) (pciexp_wake_sts): This bit is set by hardware to indicate that the system woke due to a PCI Express wakeup event. This event can be caused by the PCI Express WAKE# pins (PMU_WAKE_B, PCI_WAKE1_B, PCI_WAKE2_B, PCI_WAKE3_B) being active, or one or more of the PCI Express ports being in beacon state, or receipt of a PCI Express PME message at root port. This bit should only be set when one of these events causes the system to transition from a non-S0 system power state to the S0 system power state. This bit is set independent of the PCIEXP_WAKE_DIS bit. Software writes a 1 to clear this bit. If one of the WAKE# pins is still active during the write or one or more PCI Express ports is in the beacon state or PME message received indication is not cleared in the root port, then the bit will remain Power Management active (i.e. all inputs to this bit are level sensitive) Note: This bit does not itself cause a wake event or prevent entry to a sleeping state. Thus if the bit is 1 and the system is put into a sleeping state, the system will not automatically wake. reset_type=pmc_global_rst_b
13	0b RW	USB clockless Wake Status (USB_CLKLESS_STS) (usb_clkless_sts): This bit is set by hardware to indicate that the system woke due to change in USB serial lines. This bit is set independent of the USB_CLKLESS_EN bit. Software writes a 1 to clear this bit. reset_type=pmc_global_rst_b
12	0b RO	reserved: Reserved.
11	0b RW	Power Button Override (PWRBTNOR_STS) (pwrbtnor_sts): This bit is set any time a Power Button Override Event occurs (i.e. the power button is pressed for at least 4 consecutive seconds), or due to an internal thermal sensor catastrophic condition. These events cause an unconditional transition to the S5 state. The BIOS or SCI handler clears this bit by writing a 1 to it. This bit is not affected by hard resets via CF9h writes, and is not reset by RSMRST_B. Thus, this bit is preserved through power failures. Note that this bit is still asserted when the global SCI_EN is set to '1' then an SCI will be generated. reset_type=SRPCRST_B
10	0b RW	RTC Status (RTC_STS) (rtc_sts): This bit is set when the RTC generates an alarm (assertion of the IRQ8# signal), and is not affected by any other enable bit. See RTC_EN for the effect when RTC_STS goes active. This bit is only set by hardware and can only be reset by writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. reset_type=RSMRST_B
9	0b RO	reserved1: Reserved.
8	0b RW	Power Button Status (PWRBTN_STS) (pwrbtn_sts): This bit is set when the PMU_PWRBTN_B signal is asserted (low), independent of any other enable bit. See PWRBTN_EN for the effect when PWRBTN_STS goes active. PWRBTN_STS is always a wake event. This bit is only set by hardware and can be cleared by software writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. If the PMU_PWRBTN_B signal is held low for more than 4 seconds, the PMC clears the PWRBTN_STS bit, sets the PWRBTNOR_STS bit, the system transitions to the S5 state, and only PMU_PWRBTN_B is enabled as a wake event. If PWRBTN_STS bit is cleared by software while the PMU_PWRBTN_B pin is still held low, this will not cause the PWRBTN_STS bit to be set. The PMU_PWRBTN_B signal must go inactive and active again to set the PWRBTN_STS bit. Note that the CPU Thermal Trip and the Internal Thermal Sensors' Catastrophic Condition result in behavior matching the Powerbutton Override, which includes clearing this bit. reset_type=RSMRST_B
7:6	0b RO	reserved2: Reserved.
5	0b RW	GBL Status (GBL_STS) (gbl_sts): This bit is set when an SCI is generated due to the BIOS wanting the attention of the SCI handler. BIOS has a corresponding bit, BIOS_RLS, which will cause an SCI and set this bit. The SCI handler should then clear this bit by writing a 1 to it. This bit will not cause wake events or SMI#. This bit is not effected by SCI_EN. Note: GBL_STS being set will cause an SCI, even if the SCI_EN bit is not set. Software must take great care not to set the BIOS_RLS bit (which causes GBL_STS to be set) if the SCI handler is not in place. reset_type=PMU_PLTRST_B
4:1	0b RO	reserved3 (rserved3): reserved

Bit Range	Default & Access	Description
0	0b RW	Timer Overflow Status (TMROF_STS) (tmrof_sts) : This is the timer overflow status bit. This bit gets set anytime bit 22 of the 24 bit timer goes low (bits are counted from 0 to 23). This will occur every 2.3435 seconds. See TMROF_EN for the effect when TMROF_STS goes active. Software clears this bit by writing a 1 to it. reset_type=PMU_PLTRST_B

Bit Range	Default & Access	Description
31	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts7) : These bits are set any time the corresponding Core GPIO is set up as an input and the corresponding GPIO signal is asserted. Core GPIO pins are: SATA_GP0 (GPIO core 0) SATA_GP1 (GPIO core 1) SATA_LEDN (GPIO core 2) PCIE_CLKREQ0B (GPIO core 3) PCIE_CLKREQ1B (GPIO core 4) PCIE_CLKREQ2B (GPIO core 5) PCIE_CLKREQ3B (GPIO core 6) PCIE_CLKREQ4B (GPIO core 7) If the corresponding enable bit is set in the GPE0a_EN register, then when the CORE_GPIO_STS[n] bit is set, an SCI will be caused, depending on the GPIO_ROUT bits for the corresponding GPIO. These bits are sticky bits and are cleared by writing a 1 back to this bit position. reset_type=Resume Well Reset#
30	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts6) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
29	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts5) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
28	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts4) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
27	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts3) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
26	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts2) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
25	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts1) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
24	0b RW	CORE GPIO Status (CORE_GPIO_STS) (core_gpio_sts0) : These bit is part of CORE GPIO Status (CORE_GPIO_STS)
23	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts7) : These bits are set any time the corresponding Sus GPIO is set up as an input and the corresponding GPIO signal is asserted. Sus GPIO pins are GPIO_SUS0-7. If the corresponding enable bit is set in the GPE0a_EN register, then when the SUS_GPIO_STS[n] bit is set: * If the system is in an S3-S5 state, the event will also wake the system. * If the system is in an S0 state (or upon waking back to an S0 state), an SCI will be caused, depending on the GPIO_ROUT bits for the corresponding GPI. These bits are sticky bits and are cleared by writing a 1 back to this bit position. reset_type=Resume Well Reset#
22	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts6) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
21	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts5) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
20	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts4) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
19	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts3) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
18	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts2) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
17	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts1) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
16	0b RW	SUS GPIO Status (SUS_GPIO_STS) (sus_gpio_sts0) : These bits are part of SUS GPIO Status (SUS_GPIO_STS)
15:14	0b RO	reserved (reserved4) : Reserved.

Bit Range	Default & Access	Description
13	0b RW	Power Management Event Bus 0 Status (PME_B0_STS) (pme_b0_sts) : This bit will be set to 1 by the PMC when any internal device with PCI Power Management capabilities on bus 0 asserts the equivalent of the PME# signal. Additionally, if the PME_B0_EN and SCI_EN bits are set, and the system is in an S0 state, then the setting of the PME_B0_STS bit will generate an SCI (or SMI# if SCI_EN is not set). This bit is cleared by a software write of '1'. Internal devices which can set this bit: - Integrated LAN - HD Audio - SATA - USB
12:11	0b RO	reserved (reserved3) : Reserved.
10	0b RW	Battery Low Status (BATLOW_STS) (batlow_sts) : This bit will be set to 1 by hardware when the PMU_BATLOW_B signal goes low. Software clears the bit by writing a 1 to the bit position. In Desktop Mode, this bit will be treated as Reserved.
9	0b RW	PCI Express Status (PCI_EXP_STS) (pci_exp_sts) : This bit will be set to 1 by hardware to indicate that: - The PME event message was received on one or more of the PCI-Express Ports Note: The PCI_PMU_WAKE_B pin and the PCI-Express Beacons have no impact on this bit. Software attempts to clear this bit by writing a 1 to this bit position. If the bit is not cleared and the corresponding PCI_EXP_EN bit is set, the level-triggered SCI will remain active. Note that a race condition exists where the PCI Express device sends another PME message because the PCI Express device was not serviced within the time when it must resend the message. This may result in a spurious interrupt, and this is comprehended and approved by the PCI Express specification. The window for this race condition is approximately 95-105 milliseconds.
8	0b RW	PCI Express Wake3 Status (PCI_WAKE3_STS) (pcie_wake3_sts) : This bit is set by hardware to indicate that the PCI_WAKE3_B pin was asserted. Software writes a 1 to clear this bit. If PCI_WAKE3_B pin is still active during the write, then the bit will remain active (i.e. input to this bit is level sensitive). reset_type=pmc_global_rst_b
7	0b RW	PCI Express Wake2 Status (PCI_WAKE2_STS) (pcie_wake2_sts) : This bit is set by hardware to indicate that the PCI_WAKE2_B pin was asserted. Software writes a 1 to clear this bit. If PCI_WAKE2_B pin is still active during the write, then the bit will remain active (i.e. input to this bit is level sensitive). reset_type=pmc_global_rst_b
6	0b RW	PCI Express Wake1 Status (PCI_WAKE1_STS) (pcie_wake1_sts) : This bit is set by hardware to indicate that the PCI_WAKE1_B pin was asserted. Software writes a 1 to clear this bit. If PCI_WAKE1_B pin is still active during the write, then the bit will remain active (i.e. input to this bit is level sensitive). reset_type=pmc_global_rst_b
